Least-Squares for Second Order Elliptic Problems

James H. Bramble,* Raytcho D. Lazarov,* and Joseph E. Pasciak *

January 30, 1997

Abstract

We introduce and study two least-squares methods for second order elliptic differential equations with mixed boundary conditions. We cover also the case in which an oblique derivative is prescribed. We assume that the main part of the elliptic operator is symmetric but we do not impose any special conditions on the lower order terms except uniqueness of the solution.

The first least-squares method involves a discrete, computable $H^{-1}$-norm of the residual and stabilization terms consisting of the jumps at the interelement boundaries and weighted elementwise $L^2$-norm of the residual over the finite elements.

Next we introduce a least-squares method with the flux as an additional unknown. This method is similar to the least-squares method for first order systems introduced in [7]. It is more general in the following respects: (1) Discontinuous finite elements are allowed and (2) the Neumann and oblique derivative boundary conditions are naturally incorporated in the bilinear form so that the finite element spaces need not satisfy these conditions.

Both methods are unconditionally stable (no conditions on the step-size $h$) and optimal convergence rates are proved.

1 Introduction.

In recent years there has been significant interest in least-squares methods, considered as an alternative to the saddle point formulations and circumventing the inf-sup condition. Examples of application of the least-squares to potential flows, convection-diffusion problems, Stokes and Navier-Stokes equations can be found in [4], [3], [10], [14], [15], [17], [18]. In general, the corresponding problem is written as a system of partial differential equations of first order with possibly additional compatibility conditions. There is a variety of different approaches for introducing and studying least-squares methods for systems of first order.

Aziz, Kellogg and Stephens in [2] applied the general theory of elliptic boundary value problems of Agmon-Douglas-Nirenberg (ADN) and reduced

*Department of Mathematics, Texas A&M University, College Station, TX 77843-3368
the system to a minimization of a least-squares functional that consists of a weighted sum of the residuals occurring in the equations and the boundary conditions. The weights occurring in the least-squares functional are determined by the indices that enter into the definition of the ADN boundary value problem. This approach generalizes both the least-squares method of Jespersen [16], which is for the Poisson equation written as a \( \text{grad} - \text{div} \) system, and the method of Wendland [24], which is for elliptic systems of Cauchy-Riemann type. Recently, Bochev and Gunzburger [3], [4], have extended the ADN approach to velocity-vorticity-pressure formulation of Stokes and Navier-Stokes equations.

Another approach, mostly used for second order elliptic problems written as systems of first order, introduces a least-squares functional and studies the resulting minimization problem in the framework of the Lax-Milgram theory establishing the boundness and the coercivity of the corresponding bilinear form in an appropriate space. This approach has been used by Pehlivanov, Carey and their collaborators in [19] [20] and Cai, et al in [8], [9].

Recently, Bramble, Lazarov, and Pasciak in [7] have introduced and studied a new least-squares norm for systems arising from convection–diffusion and reaction–diffusion equations into a system of equations of first order. The least-squares functional studied there involved a discrete inner product related to the inner product in the Sobolev space \( H^{-1}(\Omega) \). The use of such an inner product results in a method which is optimal with respect to the required regularity as well as the order of approximation and extends to problems with low regularity solutions. In addition, the discrete system of equations which needs to be solved in order to compute the resulting approximation is easily preconditioned thus providing an efficient method for solving the algebraic equations. The preconditioner for the algebraic system corresponding to the new least-squares system only requires the construction of preconditioners for standard second order problems, a task which is well understood.

In fact, the first computable \( H^{-1} \)-norm was used by R. Falk in [12] to treat in a weak form the incompressibility condition \( \nabla \cdot \mathbf{u} = 0 \) for Stokes problems. The essence of this early result is that the incompressibility condition is represented in the bilinear form by the sum of its \( L^2 \)-norm and weighted by the factor \( h^{-2} \) times the discrete \( H^{-1} \)-norm. This leads to a stable scheme of optimal convergence order for linear finite elements.

In this paper, we provide a different approach from that of [7] for deriving least-squares methods for second order problems. This approach is more closely coupled to the Galerkin method. To contrast these two approaches, we study a somewhat more general problem.

Let \( \Omega \) be a bounded polygonal or polyhedral domain in \( d \) dimensional Eu-
clidean space (for \(d = 2\) or \(d = 3\)) with boundary \(\partial \Omega = \Gamma_D \cup \Gamma_N\). We shall consider the following second order elliptic boundary value problem.

\[
Lu = f \quad \text{in} \quad \Omega,
\]

\[
u = 0 \quad \text{on} \quad \Gamma_D,
\]

\[
u + \alpha(x)u_t + \beta(x)u = 0 \quad \text{on} \quad \Gamma_N.
\]

Here \(u_\nu\) denotes the outward co-normal derivative on \(\partial \Omega\) and \(u_t\) denotes the derivative along a tangential direction \(t\). The operator \(L\) is given by

\[
Lu = -\nabla \cdot A \nabla u + b \cdot \nabla u + cu
\]

\[
\equiv -\nabla \cdot A \nabla u + Xu.
\]

We assume that the matrix \(A(x)\) is symmetric, uniformly positive definite, and bounded. We also assume that \(b \in (L^\infty(\Omega))^d\) and that \(\beta\) and \(\alpha_t\) belong to \(L^\infty(\partial \Omega)\).

The development of least-squares methods is inherently coupled to various \textit{a priori} inequalities. The methods of [7] are based on the inequality (see, Lemma 2.11 of [7])

\[
C_0(\|\delta\|_0^2 + \|v\|_1^2) \leq \|\nabla \cdot \delta + Xu\|_1^2 + \| \mathcal{A}^{-1/2}(\delta + Av) \|_0^2
\]

(1.2)

The norms above are Sobolev norms (see Section 2). The inequality (1.2) as stated in [7] only holds for functions \(\delta\) in \(H_{\text{div}}(\Omega)\) satisfying \(\delta \cdot n = 0\) on \(\Gamma_N\). Here \(n\) is the outward unit normal vector. This means that the methods of [7] do not apply when either \(\alpha\) or \(\beta\) is not identically zero.

The inequality (1.2) is related to the first order system which is equivalent to (1.1), i.e.,

\[
\theta + A \nabla u = 0
\]

\[
\nabla \cdot \theta + Xu = f.
\]

(1.3)

In contrast, the methods developed in this paper are derived from the original second order operator and are based on the \textit{a priori} inequality

\[
\|v\|_1^2 \leq C \|\mathcal{L}v\|_{L^2}^2.
\]

The operator \(\mathcal{L}\) above involves the boundary conditions as well as the differential part \(L\). The resulting least-squares methods have a number of advantages. First, they extend to Robin and oblique derivative boundary conditions without complications, i.e., nonzero \(\alpha\) and \(\beta\). Secondly, since the \textit{a priori} inequality only involves one variable, it is possible to develop a least-squares method without introducing the “flux” variable \(\theta\) in (1.3). Least-squares methods involving the flux variable \(\theta\) will also be developed for applications when \(\theta\) is of
interest in itself. In contrast to those of [7], the flux approximation subspaces need not satisfy any boundary conditions on $\Gamma_N$.

The remainder of this paper is organized as follows. In Section 2, we define notation, place precise assumptions on the problem which we are studying and present some preliminary results. In Section 3 we develop the least-squares method without any new variables. The method involving the flux variable is developed in Section 4. Finally, the results of some numerical experiments are given in Section 5.

2 Preliminaries and further assumptions.

We assume that each edge (respectively face when $d = 3$) of $\Gamma_N$ on which $\alpha(x)$ is not identically zero is completely surrounded by $\Gamma_D$. In addition, we assume that the tangential direction $\mathbf{t}$ varies smoothly on these regions. Finally, when $\alpha(x)$ is not identically zero, we assume that the boundary $\partial \Omega$ is Lipschitz continuous. This makes the problem variational (cf., §4.4.3 of [13]).

To describe and analyze the least-squares method, we shall use certain Sobolev spaces. For nonnegative integers $s$, let $H^s(\bar{\Omega})$ denote the Sobolev space of order $s$ defined on a domain $\bar{\Omega}$ (see, e.g., [7]). The norm in $H^s(\bar{\Omega})$ will be denoted by $\| \cdot \|_{s, \bar{\Omega}}$. When $\Omega = \bar{\Omega}$, we simplify the notation to $\| \cdot \|_s$. In the case of $L^2(\bar{\Omega})$ the norm and the inner product will be denoted by $\| \cdot \|_{\bar{\Omega}}$ and $(\cdot, \cdot)_{\bar{\Omega}}$, respectively. The subscript will be dropped in the case when $\Omega = \bar{\Omega}$.

For noninteger values of $s$, $H^s(\bar{\Omega})$ is defined to be the functions in $H^2(\bar{\Omega})$ for which the norm

$$
\|v\|_s := \left( \|v\|_2^2 + \sum_{|\alpha| \leq s} \int_\Omega \int_\Omega \frac{|D^\alpha v(x) - D^\alpha v(y)|^2}{|x-y|^{d+2\sigma}} \, dx \, dy \right)^{1/2}
$$

is finite. Here $\lfloor s \rfloor$ is the largest integer less than $s$ and $\sigma = s - \lfloor s \rfloor$. We use the same notations for the norms and inner products for vector valued functions. For example, if $\delta$ is a vector valued functions with component $\delta_i \in H^s(\Omega)$, then

$$
\|\delta\|_s^2 := \sum_{i=1}^d \|\delta_i\|_s^2.
$$

Similarly,

$$(\delta, \eta) = \sum_{i=1}^d (\delta_i, \eta_i).$$

The weak solution of (1.1) is in the space $W$ which is defined to be the closure of

$$\{v \in C^\infty(\Omega) : v = 0 \text{ on } \Gamma_D \}$$
with respect to the norm in $H^1(\Omega)$. In the case where $\Gamma_D$ is empty and 
$\alpha \equiv \beta \equiv 0$, we define $W$ to be the set of functions in $H^1(\Omega)$ with zero mean value. The space $H^{-1}(\Omega)$ is defined by duality and consists of the functionals $v$ for which the norm

$$
\|v\|_{-1} = \sup_{\varphi \in W} \frac{(v, \varphi)}{\|\varphi\|_1}
$$

(2.1)
is finite, where $(v, \varphi)$ is the value of the functional at $\varphi$. If $v \in L^2(\Omega)$ then $(\cdot, \cdot)$ is identified with the $L^2(\Omega)$-inner product.

For any $u, v \in W$, we define the bilinear form

$$
A(u, v) = (A \nabla u, \nabla v) + (Xu, v) + \langle \alpha u_t + \beta u, v \rangle_{\Gamma_N}.
$$

(2.2)

Here $(\cdot, \cdot)_{\Gamma_N}$ denotes the inner product in $L^2(\Gamma_N)$ or the pairing of certain appropriate Sobolev spaces with their duals.

In this paper, we shall repeatedly use the fact that the bilinear form $A$ is bounded with respect to the norm in $H^1(\Omega)$. This follows from the §4.4.3 of [13] and is stated in the following lemma.

**Lemma 2.1** The bilinear form $A(\cdot, \cdot)$ is continuous on $W \times W$.

Note that the oblique derivative term in (2.2) is not a compact perturbation. This term has the same strength as $(A \nabla u, \nabla v)$.

The weak formulation of (1.1) is: Given $f \in H^{-1}(\Omega)$, find $u \in W$ satisfying

$$
A(u, \theta) = (f, \theta) \quad \text{for all } \theta \in W.
$$

(2.3)

The adjoint weak formulation of (1.1) is: Given $f \in H^{-1}(\Omega)$, find $u \in W$ satisfying

$$
A(\theta, u) = (f, \theta) \quad \text{for all } \theta \in W.
$$

(2.4)

We assume that the solutions of (2.3) and (2.4) are unique. This means that if $v \in W$ and satisfies $A(v, \theta) = 0$ or $A(\theta, v) = 0$ for all $\theta \in W$, then $v = 0$.

The particular space $H^{-1}(\Omega)$ chosen above is related to the boundary conditions used in (1.1). Following [7], we give an alternative characterization of the norm in $H^{-1}(\Omega)$. Let $D(\cdot, \cdot)$ denote the inner product in $W$, i.e.,

$$
D(u, \theta) = (u, \theta) + (\nabla u, \nabla \theta), \quad \text{for all } u, \theta \in W.
$$

(2.5)

Let $T : H^{-1}(\Omega) \mapsto W$ be defined by $Tf = u$ where $u \in W$ is the unique function satisfying

$$
D(u, \theta) = (f, \theta), \quad \text{for all } \theta \in W.
$$
As observed in [7],

\[(u, Tu) = \|u\|_{-1}^2 \quad \text{for all } u \in H^{-1}(\Omega).\]

Let the operator \( \mathcal{L} : H^1(\Omega) \to H^{-1}(\Omega) \) be defined by the identity

\[
(\mathcal{L}u, \varphi) = A(u, \varphi) \quad \text{for all } \varphi \in W.
\]

(2.6)

The following lemma plays a fundamental role in the least-squares methods which will be developed in this paper.

**Lemma 2.2** There exists a constant \( C \) independent of \( v \in W \) such that

\[
\|v\|_1 \leq C \sup_{\varphi \in W} \frac{A(v, \varphi)}{\|\varphi\|_1} = C\|\mathcal{L}v\|_{-1}
\]

(2.7)

and

\[
\|v\|_1 \leq C \sup_{\varphi \in W} \frac{A(\varphi, v)}{\|\varphi\|_1}.
\]

(2.8)

**Proof:** First, we note that for \( v \) in \( W \),

\[
(\mathcal{X}v, v) = (b \cdot \nabla v, v) + (cv, v) \leq C\|v\|_1 \|v\|_1.
\]

(2.9)

In addition,

\[
\langle \alpha v_t + \beta v, v \rangle_{\Gamma_N} = \langle \beta v, v \rangle_{\Gamma_N} - \frac{1}{2} \langle \alpha v_t, v \rangle_{\Gamma_N}
\]

\[
\leq C\|v\|_0^2\|\Gamma_N\| \leq C\|v\|_{0, \Gamma_N} \|v\|_1.
\]

(2.10)

We will prove the inequality

\[
\|v\|_1 \leq C \|\mathcal{L}v\|_{-1}
\]

(2.11)

by contradiction. If (2.11) does not hold then for every integer \( i > 0 \) there is a \( v_i \in W \) such that \( \|v_i\|_1 = 1 \) and \( \|\mathcal{L}v_i\|_{-1} \leq 1/i \). It follows from (2.9), (2.10) and obvious manipulations that for any \( v \in W \),

\[
C\|v\|_1^2 \leq (\mathcal{A}\nabla u, \nabla v) = A(v,v) - (\mathcal{X}v, v) - \langle \alpha v_t + \beta v, v \rangle_{\Gamma_N}
\]

\[
\leq A(v,v) + C (\|v\|_{0,\Gamma_N} + \|v\|) \|v\|_1.
\]

(2.12)

Thus,

\[
\|v\|_1 \leq C \left( \|\mathcal{L}v\|_{-1} + \|v\|_{0,\Gamma_N} + \|v\| \right) \leq C \left( \|\mathcal{L}v\|_{-1} + \|v\|_s \right),
\]

(2.13)
for any fixed \( s \) with \( 1/2 < s < 1 \). In the last inequality we have used a well known trace inequality (cf. [1]). Since \( \{v_i\} \) is a bounded sequence in \( H^1(\Omega) \) and \( H^1(\Omega) \) is compactly imbedded in \( H^s(\Omega) \) for \( s < 1 \), there is a subsequence denoted again by \( \{v_i\} \) which is convergent in \( H^s(\Omega) \) to \( v \). The inequality (2.13) applied to \( v_j - v_i \) shows that \( v_i \) is a Cauchy sequence in \( W \) and therefore \( v_j \to v \) in \( W \subset H^1(\Omega) \). Clearly, by Lemma 2.1, for any \( \varphi \in W \),

\[
0 = \lim_{i \to \infty} A(v_i, \varphi) = A(v, \varphi).
\]

Thus by uniqueness, \( v = 0 \) which contradicts

\[
\|v\|_1 = \lim_{i \to \infty} \|v_i\|_1 = 1.
\]

The argument for the second inequality of the lemma is analogous. This completes the proof of the Lemma 2.2. \( \square \)

Lemmas 2.1 and 2.2 together with the generalized Lax-Milgram Theorem imply the existence of the solution \( u \) of (2.3).

3 A Least-Squares Finite Element Method Without Additional Unknowns.

To approximately solve (1.1), we introduce the subspace \( W_h \subset W \) indexed by \( h \) in the interval \( 0 < h < 1 \). We do this by partitioning the domain \( \Omega \) into a set of triangles or tetrahedra \( T = \{\tau\} \). For convenience, we will use the term triangle to refer to either a triangle when \( d = 2 \) or a tetrahedron when \( d = 3 \).

Let \( h_\tau \) denote the diameter of the triangle \( \tau \). The mesh parameter \( h \) is defined to be

\[
h = \max_{\tau \in T} h_\tau.
\]

As usual, the boundaries of two triangles or tetrahedra will intersect at either a vertex, an entire edge or an entire face. We assume that the triangulations are locally quasi-uniform. By this we mean that there is a constant \( 0 < c < 1 \) such that each triangle contains a ball of radius \( ch_\tau \). Spaces defined with respect to rectangular or parallelepiped partitioning of \( \Omega \) pose no additional difficulty.

For some integer \( r \geq 2 \), let \( W_h \) denote the functions which are piecewise polynomials of degree less than \( r \) with respect to the triangles, continuous on \( \Omega \), and vanish on \( \Gamma_D \). There is a nodal basis associated with these spaces (see., e.g., [11]) and a corresponding nodal interpolation operator.

The following low order approximation and boundedness result can be proved. Given \( \varphi \in W \), there exist \( \varphi_h \in W_h \) and a constants \( C_2 \) not dependent on \( h \) and \( v \) such that

\[
\sum_{\tau \in T} \left\{ h_\tau^{-2} \| \varphi - \varphi_h \|_{l_\tau}^2 + \| \varphi - \varphi_h \|_{1, l_\tau}^2 \right\} \leq C_2 \| \varphi \|_1^2.
\]  

(3.1)
The arguments which can be used to prove this result in the quasi-uniform case are given in [6] and the general case is given in the proof of Lemma 4.1.1 of [25].

To develop the least-squares method, we shall need additional discrete norms and inner products. For \( v \in W_h \), the discrete negative norm is given by

\[
\|v\|_{-1,h} = \sup_{\varphi_h \in W_h} \frac{(v, \varphi_h)}{\|\varphi_h\|_1}. \tag{3.2}
\]

This norm extends to a semi-norm on \( H^{-1}(\Omega) \) which is bounded by the norm \( \| \cdot \|_{-1} \). In addition, we define a weighted \( L^2 \) norm,

\[
\|v\|_h = \left( \sum_i h_i^2 \|v\|_{\frac{2}{\gamma_i}}^2 \right)^{1/2}. \tag{3.3}
\]

The inner product corresponding to this norm shall be denoted by \((\cdot, \cdot)_h\). This norm will often be applied to derivatives of functions which are piecewise smooth with respect to the triangulation. In such cases, the differentiation will be done on an element by element basis.

We will also need edge norms and inner products. Let \( \{\epsilon_i\} \) be the collection of the interior edges (respectively, faces) in the partitioning of \( \Omega \) into triangles (respectively, tetrahedra). We introduce the bilinear form

\[
\langle u, v \rangle_{h,I} = \sum_i h_{\tau(\epsilon_i)} \int_{\epsilon_i} uv \, ds \tag{3.4}
\]

where the summation is over the set of all interior edges (respectively, faces) \( \{\epsilon_i\} \). Here \( \tau(\epsilon_i) \) is a triangle or tetrahedron which has \( \epsilon_i \) as an edge or face. Similarly,

\[
\langle u, v \rangle_{h,I,N} = \sum_i h_{\tau(\epsilon_i)} \int_{\epsilon_i} uv \, ds \tag{3.5}
\]

where the summation is over the set of all edges (respectively, faces) on \( \Gamma_N \). The corresponding seminorms are denoted

\[
\|v\|_{h,I} = \langle u, v \rangle_{h,I}^{1/2} \quad \text{and} \quad \|v\|_{h,I,N} = \langle u, v \rangle_{h,I,N}^{1/2}. \tag{3.6}
\]

Let the operator \( \mathcal{L}_h : W \to W_h \) be defined by

\[
(\mathcal{L}_h v, \varphi_h) = A(v, \varphi_h) \quad \text{for all } \varphi_h \in W_h. \tag{3.7}
\]

We then have the following \textit{a priori} inequality.
Lemma 3.1 There exists a constant $C$ not depending on $h$ such that for any $v \in W_h$

$$
\|v\|_1^2 \leq C \left\{ \|L_h v\|_{-1,h}^2 + \|[v]\|_{h,T}^2 + \|Lv\|_h^2 + \|v\|_{h,T}^2 + \|Lv\|_h^2 + \|v\|_{h,T}^2 \right\}.
$$ (3.8)

Here $[u_v]$ denotes the jump in the co-normal derivative $u_v$ across an interior edge.

Proof: The argument is almost the same as the proof of Theorem 1 of [5]. By Lemma 2.2, it suffices to show that for $v \in W_h$,

$$
|A(v, \phi)| \leq C \left\{ \|L_h v\|_{-1,h} + \|[v]\|_{h,T} + \|Lv\|_h \right\} \|\phi\|_1.
$$ (3.9)

For $\varphi \in W$ let $\varphi_h \in W_h$ be a function which satisfies the inequalities (3.1). It follows that

$$
|A(v, \varphi)| = |A(v, \varphi - \varphi_h) + A(v, \varphi_h)|
$$

$$
\leq |A(v, \varphi - \varphi_h)| + \|L_h v\|_{-1,h} \|\varphi_h\|_1
$$

$$
\leq |A(v, \varphi - \varphi_h)| + C \|L_h v\|_{-1,h} \|\varphi\|_1.
$$ (3.10)

Integrating by parts element-by-element gives

$$
A(v, \varphi - \varphi_h) = \sum_{\tau_i \in T} \left\{ \int_{\tau_i} (-\nabla \cdot \nabla v + \chi v)(\varphi - \varphi_h) \, dx + \int_{\partial \tau_i} v\nu(\varphi - \varphi_h) \, ds \right\}
$$

$$
+ \sum_{e_k \subset \Gamma_N} \int_{e_k} (\alpha v + \beta v)(\varphi - \varphi_h) \, ds
$$

$$
= \sum_{\tau_i \in T} \int_{\tau_i} Lv(\varphi - \varphi_h) \, dx + \sum_{j} \int_{e_j} [v](\varphi - \varphi_h) \, ds
$$

$$
+ \sum_{e_k \subset \Gamma_N} \int_{e_k} (v\nu + \alpha v + \beta v)(\varphi - \varphi_h) \, ds
$$ (3.11)

We bound the terms on the right hand side of (3.11) separately. For the first,

$$
\sum_{\tau_i \in T} \left| \int_{\tau_i} Lv(\varphi - \varphi_h) \, dx \right| \leq C \sum_{\tau_i \in T} h_{\tau_i} \|Lv\|_{\tau_i} \|\varphi\|_{1,\tau_i}
$$

$$
\leq C \|Lv\|_h \|\varphi\|_1.
$$ (3.12)

For the second, we use the well-known inequality

$$
\int_{\partial \tau_i} |\theta|^2 \, ds \leq C \left( h_{\tau_i}^{-1} \|\theta\|_{\tau_i}^2 + h_{\tau_i} \|\theta\|_{1,\tau_i}^2 \right).
$$ (3.13)
Combining this with (3.1) gives
\[
\sum_j \left| \int_{\epsilon_j} [v_{\nu} - \varphi_h] \, ds \right| \leq C \sum_j h_{\epsilon_j}^{1/2} \|v_{\nu}\| \|\varphi\|_{1, \Gamma_\epsilon(\epsilon_j)}.
\]
\[
\leq C \|v_{\nu}\|_{h, \Gamma} \|\varphi\|_1.
\]  
(3.14)

Similarly,
\[
\sum_{\epsilon_k \subset \Gamma_N} \left| \int_{\epsilon_k} (v_{\nu} + \alpha v_t + \beta v)(\varphi - \varphi_h) \, ds \right| \leq C \sum_{\epsilon_k \subset \Gamma_N} h_{\epsilon_k}^{1/2} \|v_{\nu} + \alpha v_t + \beta v\| \|\varphi\|_{1, \Gamma_N(\epsilon_k)}
\]
\[
\leq C \|v_{\nu} + \alpha v_t + \beta v\|_{h, \Gamma_N} \|\varphi\|_1.
\]  
(3.15)

Combining (3.10)–(3.15) proves (3.9) and hence completes the proof of the lemma. □

**Remark 3.1** The last three terms on the right hand side of (3.8) are stabilizing terms. It is known that the Galerkin method is stable in $H^1(\Omega)$ (see, [21],[23]) if $h \leq h_0$ is sufficiently small. This means that the Galerkin solution $V \in W_h$ satisfying
\[
A(\theta, V) = D(\theta, u) \quad \text{for all } \theta \in W_h
\]  
(3.16)

can be bounded by
\[
\|V\|_1 \leq C \|v\|_1 \leq C \|u\|_1
\]
where $v$ is the continuous solution of (3.16) ($v \in W$ satisfies (3.16) for all $\theta \in W$). If $u \in W_h$ with $h \leq h_0$ then
\[
\|u\|_1 = \frac{A(u, V)}{\|u\|_1} \leq C \frac{A(u, V)}{\|V\|_1} \leq C \|\mathcal{L}_h u\|_{-1, h}.
\]

Thus, for $h \leq h_0$, the stabilizing terms are not necessary.

Before describing the least-squares method suggested by the previous lemma we provide an equivalent discrete negative norm. As in the continuous case, the discrete negative norm can be alternatively characterized in terms of a certain operator. Specifically, let $T_h : H^{-1}(\Omega) \rightarrow W_h$ be defined by $T_h f = w$ where $w$ is the unique element of $W_h$ satisfying
\[
D(w, \theta) = (f, \theta) \quad \text{for all } \theta \in W_h.
\]
Note that $T_h$ is the finite element analogue of the operator $T$ and that

$$\|v\|_{-1,h}^2 = (v, T_h v) \quad \text{for all } v \in H^{-1}(\Omega).$$

Note also that for $v \in L^2(\Omega)$, $(v, T_h v) = (T_h v, v)$.

Although one can develop the least-squares algorithms in terms of $T_h$, it is often more computationally efficient to replace this operator by a preconditioner $B_h$. To this end, we assume that we are given an operator $B_h : W_h \mapsto W_h$ which is a symmetric, positive definite operator with respect to the $L^2(\Omega)$ inner product and spectrally equivalent to $T_h$. This means that there are positive constants $C_4, C_5$ not depending on $h$ and satisfying

$$C_4(T_h w, w) \leq (B_h w, w) \leq C_5(T_h w, w) \quad \text{for all } w \in W_h. \quad (3.17)$$

A good preconditioner is also computationally less expensive to evaluate. Examples of good preconditioners result from multigrid and domain decomposition algorithms.

We define the first least-squares bilinear form on $W_h \times W_h$ by

$$Q_1(u, v) \equiv (B_h \mathcal{L}_h u, \mathcal{L}_h v) + (Lu, Lv)_h + \langle [u_v], [v_v] \rangle_{h,I}$$

$$+ \langle u_v + \alpha v_t + \beta u, v_v + \alpha v_t + \beta v \rangle_{h,\Gamma_N}. \quad (3.18)$$

The corresponding least-squares method follows.

**Least-Squares Method without Additional Unknowns:** Find $U \in W_h$ such that

$$(\mathcal{L}_h U - f, B_h \mathcal{L}_h V) + (LU - f, LV)_h + \langle [U_v], [V_v] \rangle_{h,I}$$

$$+ \langle U_v + \alpha U_t + \beta U, V_v + \alpha V_t + \beta V \rangle_{h,\Gamma_N} = 0, \quad \text{for all } V \in W_h, \quad (3.19)$$

or

$$Q_1(U, V) = (f, B_h \mathcal{L}_h V) + (f, LV)_h, \quad \text{for all } V \in W_h. \quad (3.20)$$

Note that the term $(f, LV)_h$ in the right hand side represents a sum of weighted $L^2$-inner products of $f$ and $LV$ over the finite elements $\tau \in \mathcal{T}$ and therefore it makes sense only for $f \in L^2(\Omega)$. If $f$ does not belong to $L^2(\Omega)$ then we can reformulate the least-squares method by dropping the term $(f, LV)_h$ in (3.20). Thus, in the case of nonsmooth $f$, (3.19) is reduced to the following least-squares method: Find $U \in W_h$ such that

$$Q_1(U, V) = (f, B_h \mathcal{L}_h V), \quad \text{for all } V \in W_h. \quad (3.21)$$

As we shall show later this truncated formulation has order of convergence $O(h^{\gamma-1})$ for $u \in H^{\gamma}(\Omega)$ for $1 \leq \gamma \leq 2$. 

11
Remark 3.2 The least-squares method (3.19) can be thought of as a stabilized Galerkin method. By Remark 3.1, we can drop the stabilizing terms when \( h \) is sufficiently small and use the least-squares method
\[
(\mathcal{L}_h U - f, B_h \mathcal{L}_h V) = 0 \quad \text{for all } V \in W_h.
\]
Since \( B_h \mathcal{L}_h \) is invertible, this is the same as
\[
(\mathcal{L}_h U - f, V) = 0 \quad \text{for all } V \in W_h,
\]
which is the Galerkin method applied to (1.1).

The following Lemma is a consequence of Lemmas 2.1 and 3.1 and obvious manipulations.

Lemma 3.2 The bilinear form \( Q_1(u, v) \) is symmetric, coercive, and bounded in the \( H^1 \)-norm on the finite element space \( W_h \).

3.1 Error Analysis

The above stability results lead to error estimates as we shall now demonstrate. We first introduce the following lemma.

Lemma 3.3 Let \( \hat{\Gamma} \) be a reference triangle of unit size and \( w \) be in \( H^s(\hat{\Gamma}) \) for \( s > 3/2 \). Then for any edge \( \hat{e} \) of \( \hat{\Gamma} \),
\[
\|w_\nu\|_{0,\hat{e}} \leq C \|w\|_{s,\hat{\Gamma}},
\]
\[
\|w_\nu\|_{0,\hat{e}} \leq C \|w\|_{s,\hat{\Gamma}}.
\]

Proof: We cannot simply apply trace theory since \( \partial \hat{\Gamma} \) is not a \( C^{1,1} \) boundary. Let \( \Omega \) be a domain with \( C^{1,1} \) boundary with \( \hat{\Gamma} \subset \partial \Omega \). Let \( \bar{w} \) be an \( H^s \) bounded extension of \( w \) in \( H^s(\mathbb{R}^d) \). It then follows that
\[
\|w_\nu\|_{0,\hat{e}} \leq \|\bar{w}_\nu\|_{0,\partial \Omega} \leq C \|\bar{w}\|_{s,\mathbb{R}^d} \leq C \|w\|_{s,\hat{\Gamma}}.
\]
The second inequality follows in a similar manner. This completes the proof of the lemma. \( \square \)

We now state and prove an error estimate for the least-squares method in the case of a quasi-uniform mesh. The case of sufficiently regular solutions and data is discussed in Theorem 3.1, while the case of solutions in \( H^\gamma(\Omega) \) for \( 1 \leq \gamma \leq 2 \) is discussed in Theorem 3.2.
**Theorem 3.1** Let \( u \in H^\gamma(\Omega) \) for \( 2 \leq \gamma \leq r \) and \( U \) be the solution of the least-squares method defined by (3.19). Assume that the triangulation is quasi-uniform and set \( h = \max_i h_i \). Then there exists a positive constant \( C \) not depending on \( u \) or \( h \) such that
\[
\|U - u\|_1 \leq C h^{\gamma-1} \|u\|_\gamma.
\] (3.22)

**Theorem 3.2** Assume that \( u \in H^\gamma(\Omega) \) for \( 1 \leq \gamma \leq 2 \), the triangulation is quasi-uniform with \( h = \max_i h_i \), and \( U \) is the solution of the reduced least-squares method defined by (3.21). Then there exists a positive constant \( C \) not depending on \( u \) or \( h \) such that
\[
\|U - u\|_1 \leq C h^{\gamma-1} \|u\|_\gamma.
\] (3.23)

Let \( E = U - V \) and \( e = u - V \) where \( U \) is the solution to (3.19) and \( V \in W_h \) is the interpolant (in \( W_h \)) of \( u \). Before proving the above theorems, we introduce the following lemma based on the Bramble-Hilbert Lemma. Its proof uses Lemma 3.3 and is standard.

**Lemma 3.4** Let \( \tau \) be a mesh triangle and assume that the solution \( u \) is in \( H^s(\tau) \) for some \( s \) in \([2, r]\). Then,
\[
\|e\|_{l, \tau} \leq C h^{s-l} \|u\|_{s, \tau}, \quad l = 0, 1, 2,
\]
\[
\|e_l\|_{0, \partial \tau} \leq C h^{s-3/2} \|u\|_{s, \tau}
\]
\[
\|e_v\|_{0, \partial \tau} \leq C h^{s-3/2} \|u\|_{s, \tau}
\]
\[
\|e\|_{0, \partial \tau} \leq C h^{s-1/2} \|u\|_{s, \tau}.
\] (3.24)

The constant \( C \) above can be chosen independent of \( h \) and \( \tau \).

**Remark 3.3** For an edge \( \epsilon_i \), let \( \check{\tau}(\epsilon_i) \) denote the union of triangles which have \( \epsilon_i \) as an edge. Then the above lemma implies that
\[
\|[e_v]\|_{0, \epsilon_i} \leq C h^{s-3/2} \|u\|_{s, \check{\tau}(\epsilon_i)}.
\]

**Proof (of Theorem 3.1):** Clearly,
\[
\|U - u\|_1 \leq \|E\|_1 + \|e\|_1.
\]

By Lemma 3.1,
\[
\|E\|_1 \leq C Q_1(E, E)^{1/2} \leq C \left[ Q_1(U - u, U - u)^{1/2} + Q_1(e, e)^{1/2} \right].
\]

It follows from (3.19) that
\[
Q_1(U - u, V) = 0 \quad \text{for all} \ V \in W_h.
\]

13
and hence
\[ Q_1(U - u, U - u) \leq Q_1(e, e). \]
Thus,
\[ \|E\|_1 \leq CQ_1(e, e)^{1/2}. \]
Combining the above inequalities gives
\[ \|U - u\|_1 \leq CQ_1(e, e)^{1/2} + \|e\|_1. \] (3.25)

The estimate of \( \|e\|_1 \) follows immediately from the estimate (3.24) with \( l = 1 \) and summing over all triangles.

We estimate the first term in (3.25) by examining each term in (3.18). For the first, we have
\[
(B_h \mathcal{L}_h e, \mathcal{L}_h e)^{1/2} \leq C \|\mathcal{L}_h e\|_{-1,h} = C \sup_{\phi \in W_h} \frac{(\mathcal{L}_h e, \phi)}{\|\phi\|_1} \leq C \|e\|_1.
\] (3.26)

For the second, using (3.24) with \( l = 2 \) we get
\[
(Le, Le)_h \leq C \sum_{\tau \in T} h^2\|e\|_{2,\tau}^2 \leq Ch^{2(\gamma - 1)}\|u\|_{\gamma,\Omega}^2.
\] (3.27)

Finally, since \( u \) is in \( H^\gamma(\Omega) \) for \( \gamma \in [2, r] \), it immediately follows from Lemma 3.4 and Remark 3.3 that for interior edges,
\[
h_{\tau(e)}^{1/2} \|e_{\tau(e)}\|_{0,\tau(e)} \leq Ch^{\gamma - 1}\|u\|_{\gamma,\Omega}.
\] (3.28)

and for boundary edges,
\[
h_{\tau(e)}^{1/2} \|e_{\tau(e)} + \alpha e_t + \beta e_{\tau(e)}\|_{0,\tau(e)} \leq Ch^{\gamma - 1}\|u\|_{\gamma,\Omega}.
\] (3.29)

Theorem 3.1 follows from (3.26)–(3.29), Lemma 3.4 and summation. \( \square \)

**Proof (of Theorem 3.2):** To prove the result for the reduced least-squares method (3.21) when the solution \( u \in H^\gamma(\Omega) \) for \( 1 \leq \gamma \leq 2 \), we first prove stability in \( H^1(\Omega) \), i.e.,
\[ \|U\|_1 \leq C \|u\|_1. \] (3.30)

By Lemma 3.1 and (3.21),
\[ \|U\|_1^2 \leq CQ_1(U, U) = C(f, B_h \mathcal{L} U). \] (3.31)

By (3.17),
\[ (f, B_h \mathcal{L} U) \leq C\|f\|_1 \|\mathcal{L} U\|_{-1} \leq C\|u\|_1 \|U\|_1. \] (3.32)
This proves (3.30) and the result for $\gamma = 1$ easily follows.

For $\gamma = 2$, it is enough to show that $(f, LU)_h \leq Ch\|u\|_2\|U\|_1$. This is an immediate consequence of the definition of $(\cdot, \cdot)_h$, the inverse inequality and the obvious inequality $\|f\| \leq C\|u\|_{2,\Omega}$. Since $W \cap H^2(\Omega)$, for $1 \leq \gamma \leq 2$, is a Hilbert scale, it follows by interpolation that the result holds for $1 < \gamma < 2$. This completes the proof of Theorem 3.2 □

We next illustrate that the stability estimate of Lemma 3.1 can be used to derive error estimates in the case of a refinement example. We illustrate this by considering a simple example involving piecewise linear finite element approximation. Specifically, we consider the problem: given $f \in L^2(\Omega)$ find $u$ such that

$$
-\Delta u = f \quad \text{in } \Omega, \\
u = 0 \quad \text{on } \partial \Omega.
$$

(3.33)

where $\Omega$ is defined to be the points in the square $(-1, 1) \times (-1, 1)$ which make an angle of absolute value less than $\pi - \omega$ with the positive $x$-axis. For $0 < \omega < \pi/2$, such a problem results in a singular solution of the form (see Theorem 4.4.3.7 of [13])

$$
u = c(f)r^{\gamma} \sin(\gamma \phi) \eta(r) + w
$$

(3.34)

where $(r, \phi)$ are the polar coordinates in the plane $R^2$, $\eta$ is a $C^\infty$ cutoff function which is zero for $r \geq 1$, $w \in H^2(\Omega)$ and $\bar{\gamma} = [2(1 - \omega/\pi)]^{-1}$. The constant $c(f)$ above satisfies

$$|c(f)| \leq C \|f\|_0.
$$

It follows that for $\gamma < \bar{\gamma}$

$$\|u\|_{1+\gamma} \leq C \|f\|_{-1+\gamma} \quad \text{and} \quad \|u\|_{2,\Omega} \leq C r^{\bar{\gamma}-1} \|f\|_0.
$$

Here

$$\Omega_r^* = \Omega \cap \{x \mid |x| > r\}.
$$

We now define a mesh refinement strategy in terms of a “coarse” mesh parameter $h_c$. Such a strategy has been used, e.g., in [22]. All triangles shall be assumed to be shape regular (they satisfy a minimal angle condition). We introduce $R_j = 2^{-j}$ for $j = 0, \ldots, k$, where the positive integer $k$ will be determined later. We define $\Omega_k$ to be the union of all triangles $\tau$ in $T$ such that

$$\tau \cap \{x \in \Omega \mid |x| \leq R_k\} \neq \emptyset.
$$

Roughly speaking $\Omega_k$ is an $R_k$-neighborhood of the singular point $(0, 0)$. Next for $j = k - 1, \ldots, 0$ we define $\Omega_j$ to be the union of the triangles $\tau$ in $T$ such that

$$\tau \cap \{x \in \Omega \mid R_{j+1} \leq |x| \leq R_j\} \neq \emptyset.$$
We add all unassigned triangles of $\mathcal{T}$ to $\Omega_0$.

We assume that the grid partition $\mathcal{T}$ satisfies the following property: There is a $\beta$ in the interval $(1 - \gamma, 1)$ such that for $j = 0, 1, \ldots, k$ and each triangle $\tau \cap \Omega_j \neq \emptyset$,

$$C_0 R_j^\beta h_c \leq h_\tau \leq C_1 R_j^\beta h_c. \quad (3.35)$$

with some constants $C_0$ and $C_1$ independent of $h_c$ and $k$. For example, $\beta = 0.5$ would be a good choice for all angles $0 < \omega < \pi/2$.

**Theorem 3.3** The least-squares method for problem (3.33), using a triangulation satisfying the above conditions, gives rise to an error estimate of the form

$$\| u - U \|_1 \leq C h_c \| f \|_0$$

provided that $k$ is chosen such that

$$R_k \leq h_c^{1-\beta \gamma}, \text{ i.e. } k \geq \frac{1 - \gamma}{\beta \gamma} \frac{|\ln(h_c)|}{\ln(2)}. \quad (3.36)$$

**Remark 3.4** It is easy to check that since $\beta < 1$, the number of triangles in such a mesh is bounded by a constant multiple of $h_c^{-2}$. Thus the theorem provides a quasi-optimal result in the sense that increasing the work by a fixed constant leads to the global accuracy one would expect on a smooth problem and a quasi-uniform mesh of size $h_c$.

**Proof of Theorem 3.3.** Let $V$, $E$ and $e$ be defined as in the proof of Theorem 3.1. Again, we need to bound the two terms on the right hand side of (3.25). By (3.26), this reduces to bounding

$$\| e \|_{1, \Omega_j}^2 + (\Delta e, \Delta e)_h + \langle [e_\nu], [e_\nu] \rangle_{h, \tau}.$$

We first provide an estimate on $\Omega_j$, for $j = 0, \ldots, k - 1$. Let $\mathcal{N}(\Omega_j)$ denote the union of triangles in $\mathcal{T}$ which have an edge which intersects $\Omega_j$. Applying Lemma 3.4 and Remark 3.3 shows that

$$\| e \|_{1, \Omega_j}^2 + \sum \h_{\alpha} \| [e_\nu] \|_{0, \alpha}^2 + \sum_{\tau \cap \Omega_j \neq \emptyset} h_\tau^2 \| \Delta e \|_{0, \tau}^2 \leq C R_j^{2\beta} h_c^2 \| u \|_{2, \mathcal{N}(\Omega_j)}^2 \leq C R_j^{2(\beta + \gamma - 1)} h_c^2 \| f \|_0^2. \quad (3.37)$$

The first sum above is taken over the interior edges (with respect to $\Omega$) in $\Omega_j$.  

16
In the case of $\Omega_k$, we have
\[
\|e\|^2_{1, \Omega_k} + \sum h_e \|e_v\|^2_{0, e} + \sum_{\tau \subset \Omega_k} h_t^2 \|\Delta e\|^2_{0, \tau} \\
\leq CR_k^{2\gamma} h_c^{2\gamma} (\|u\|^2_{1+\gamma} + \|f\|^2_0) \leq CR_k^{2\gamma} h_c^{2\gamma} \|f\|^2_0.
\]
(3.38)

The first sum above is taken over the interior edges (with respect to $\Omega$) in $\Omega_k$. Summing (3.37) over $j$ and using (3.38) and the fact that $\beta > 1 - \gamma$ gives
\[
\|u - U\|^2_1 \leq C(h_c^2 + R_k^{2\gamma} h_c^{2\gamma}) \|f\|^2_0.
\]
The theorem follows taking $k$ such that (3.36) holds. $\Box$

4 A Least-Squares Finite Element Method involving the Flux

In this section, we develop a least-squares method for a first order system which is equivalent to (1.1) and involves the flux variable $\theta = -A \nabla u$. To do this, we will prove a relevant a priori inequality.

Let $\delta$ be in $(L^2(\Omega))^d$. It follows from Lemma 2.2 that
\[
\|v\|_1 \leq C \sup_{\varphi \in W} \frac{A(v, \varphi)}{\|\varphi\|_1} = C \sup_{\varphi \in W} \frac{(A \nabla v + \delta, \nabla \varphi) - (\delta, \nabla \varphi) + (Xv, \varphi) + \langle \alpha v_t + \beta v, \varphi \rangle_{\Gamma_N}}{\|\varphi\|_1}.
\]
(4.1)

It is thus natural to introduce an operator $\mathcal{F} : (L^2(\Omega))^d \times W \mapsto H^{-1}(\Omega)$ defined by
\[
(\mathcal{F}(\delta, v), \varphi) = -(\delta, \nabla \varphi) + (Xv, \varphi) + \langle \alpha v_t + \beta v, \varphi \rangle_{\Gamma_N}, \quad \text{for all } \varphi \in W.
\]

Then by (4.1) and the triangle inequality
\[
\|v\|_1 \leq C \left\{ \|\delta + A \nabla v\|_0 + \|\mathcal{F}(\delta, v)\|_{-1} \right\}.
\]
(4.2)

We introduce a discrete approximation $\mathcal{F}_h$ to the operator $\mathcal{F}$. Define $\mathcal{F}_h : L^2(\Omega) \times W \mapsto W_h$ by
\[
(\mathcal{F}_h(\delta, v), \varphi) = -(\delta, \nabla \varphi) + (Xv, \varphi) + \langle \alpha v_t + \beta v, \varphi \rangle_{\Gamma_N}, \quad \text{for all } \varphi \in W_h.
\]

The following lemma will be the basis for the least-squares methods studied in this section.
Lemma 4.1 Let \( \delta \) be a function which is in \((H^1(\tau_i))^d\) for each triangle \( \tau_i \in \mathcal{T} \) and \( v \) be in \( W \). Then,

\[
\| \delta \|_0^2 + \| v \|_1^2 \leq C \left\{ \| A^{-1/2}(\delta + A\nabla v) \|_0^2 + \| \mathcal{F}_h(\delta, v) \|_{-1,h}^2 + \| \nabla \cdot \delta + \mathcal{X} v \|_h^2 \right. \\
+ \left. \| [\delta \cdot n] \|_{h,I}^2 + \| -\delta \cdot n + \alpha v_t + \beta v \|_{h,\Gamma_N}^2 \right\}. \tag{4.3}
\]

Proof: It follows immediately from (4.2) that

\[
\| v \|_1 \leq C \left\{ \| A^{-1/2}(\delta + A\nabla v) \|_0 + \| \mathcal{F}(\delta, v) \|_{-1} \right\}.
\]

Clearly then

\[
\| \delta \|_0 \leq C \left\{ \| A^{-1/2}(\delta + A\nabla v) \|_0 + \| \mathcal{F}(\delta, v) \|_{-1} \right\}.
\]

Now \( \| \mathcal{F}(\delta, v) \|_{-1} \) may be estimated by the right hand side of (4.3). To this end for \( \varphi \in W \) let \( \varphi_h \) be the element in \( W_h \) satisfying (3.1). Then by (3.1),

\[
\| \mathcal{F}(\delta, v) \|_{-1} = \sup_{\varphi \in W} \frac{\langle \mathcal{F}_h(\delta, v), \varphi_h \rangle + \langle \mathcal{F}(\delta, v), \varphi - \varphi_h \rangle}{\| \varphi \|_1} \\
\leq C \| \mathcal{F}_h(\delta, v) \|_{-1,h} + \sup_{\varphi \in W} \frac{\langle \mathcal{F}(\delta, v), \varphi - \varphi_h \rangle}{\| \varphi \|_1}. \tag{4.4}
\]

To estimate the last term in (4.4), we integrate by parts to get

\[
\langle \mathcal{F}_h(\delta, v), \varphi - \varphi_h \rangle = \langle \alpha v_t + \beta v, \varphi - \varphi_h \rangle_{\Gamma_N} \\
+ \sum_{\tau_i \in \mathcal{T}} \{ (\nabla \cdot \delta + \mathcal{X} v, \varphi - \varphi_h)_{\tau_i} - \langle \delta \cdot n, \varphi - \varphi_h \rangle_{\partial \tau_i} \}. \]

The same estimates as used in Lemma 3.1 give that

\[
\langle \mathcal{F}_h(\delta, v), \varphi - \varphi_h \rangle \leq C \left\{ \| [\delta \cdot n] \|_{h,I} + \| \nabla \cdot \delta + \mathcal{X} v \|_h \right. \\
+ \left. \| -\delta \cdot n + \alpha v_t + \beta v \|_{h,\Gamma_N} \right\} \| \varphi \|_1.
\]

Combining the above estimates completes the proof of the lemma. \( \square \)

In order to formulate a finite element least-squares method we need to define an approximation subspace \( V_h \subset (L^2(\Omega))^d \). This we choose to consist of piecewise polynomials with respect to the triangulation \( \mathcal{T} \). We only need \( r - 1 \) order approximation. Thus, we can take polynomials of degree \( r - 2 \).
The piecewise polynomial functions can be discontinuous across triangles and need not satisfy any boundary conditions on \( \Gamma_N \).

The above lemma suggests a new least-squares method with flux unknowns. Suppose that \( \theta \) is defined by (1.3) and \( u \) solves (1.1). Then

\[
\begin{align*}
\theta + \mathcal{A} \nabla u &= 0, \\
\mathcal{F}_h(\theta, u) &= F_h, \\
|\theta \cdot n| &= 0 \quad \text{on interior edges}, \\
-\theta \cdot n + \alpha u_t + \beta u &= 0 \quad \text{on } \Gamma_N.
\end{align*}
\]

Here \( F_h \) is the \( L^2(\Omega) \) projection of \( f \) onto \( W_h \). In order to simplify our notation we introduce the bilinear form \( Q_2(\zeta, w; \delta, v) \) defined on \( V_h \times W_h \) by

\[
Q_2(\zeta, w; \delta, v) = (B_h(\mathcal{F}_h(\zeta, w)), \mathcal{F}_h(\delta, v)) + (\zeta + A \nabla w, A^{-1} \delta + \nabla v) \\
+ \langle [\zeta \cdot n], [\delta \cdot n] \rangle_{\Gamma_N} + \langle -\zeta \cdot n + \alpha u_t + \beta w, -\delta \cdot n + \alpha u_t + \beta v \rangle_{\Gamma_N} \\
+ (\nabla \cdot \zeta + Xw, \nabla \cdot \delta + Xv)_h. \tag{4.5}
\]

Lemma 4.1 says that the bilinear form \( Q_2 \) is coercive and continuous in \( V_h \times W_h \) equipped with the \( (L^2)^d \) and \( H^1 \) norms. It suggests the following least-squares method.

**Least-Squares Method with Flux Unknowns:** Find \( (\zeta_h, u_h) \in V_h \times W_h \) such that

\[
Q_2(\zeta_h, u_h; \delta, v) = (f, \mathcal{F}_h(\delta, v)) + (f, \nabla \cdot \delta + Xv)_h, \\
\text{for all } (\delta, v) \in V_h \times W_h. \tag{4.6}
\]

Obviously this formulation makes sense only for \( f \in L^2(\Omega) \). For \( f \) not in \( L^2(\Omega) \), one can make a simple modification of the scheme by dropping the second term on the right-hand-side of (4.6). In this case, we get the following least-squares method: Find \( (\zeta_h, u_h) \in V_h \times W_h \) such that

\[
Q_2(\zeta_h, u_h; \delta, v) = (f, \mathcal{F}_h(\delta, v)), \quad \text{for all } (\delta, v) \in V_h \times W_h. \tag{4.7}
\]

Here \( (f, \mathcal{F}_h(\delta, v)) \) is the value of the linear functional at \( \mathcal{F}_h(\delta, v) \in W \). As we show in the next theorem the reduced formulation (4.7) converges with a rate of \( O(h^{\gamma-1}) \) for \( u \in H^{1+\gamma}(\Omega) \) and \( 1 \leq \gamma \leq 2 \).

**Remark 4.1** If \( V_h \subset V = H(\text{div}; \Omega) \), then \( |\zeta_h \cdot n| \mid_{e_j} = 0 \) and the corresponding term in the least-squares method is identically zero. Here \( e_j \) denotes an interior edge (face) of the finite element \( \tau_j \). If, in addition to \( V_h \subset V = H(\text{div}; \Omega) \) \( \alpha \equiv \beta \equiv 0 \) and the functions in \( V_h \) satisfy the boundary condition \( \zeta_h \cdot n = 0 \) on \( \Gamma_N \), then this method coincides with the least-squares method of [7]. However, the method proposed in this paper is more general than that of [7] in two respects:
1. The spaces $V_h$ are allowed to be discontinuous.

2. The Neumann and oblique derivative boundary conditions are naturally incorporated in the bilinear form and the functions in $V_h$ need not satisfy these conditions.

**Theorem 4.1** Assume that the triangulation is quasi-uniform and set $h = \max_i h_i$. If $u \in H^\gamma(\Omega)$ for $2 \leq \gamma \leq r$ then the solution $(\zeta_h, u_h)$ of the least-squares method (4.6) satisfies the estimate

$$
\|\zeta_h - \theta\|_0 + \|u_h - u\|_1 \leq Ch^{\gamma-1} \|u\|_{\gamma},
$$

with a constant $C$ independent of $u$, $\theta$, and $h$. Furthermore, if $u \in H^\gamma(\Omega)$ for $1 < \gamma \leq 2$ then the reduced method (4.7) satisfies the error estimate (4.8).

5 Numerical Results.

We provide some numerical results in this section which illustrate the convergence behavior of the least-squares methods studied in the earlier sections. Specifically, we will consider the method which does not introduce any additional unknowns (3.19).

We only report the performance of the method on a model problem with oblique derivative boundary condition. Specifically, let $\Omega$ be the unit square in $R^2$. We consider the problem of approximating solutions to

$$
-\Delta u = f \quad \text{in } \Omega \\
\frac{\partial u}{\partial n} + \frac{\partial u}{\partial t} = 0 \quad \text{on } \Gamma_N.
$$

Here $\Gamma_N$ is the right-most edge of the boundary ($x = 1$) and $\Gamma_D = \partial \Omega/\Gamma_N$.

For approximation, we use a regular grid of triangles and a subspace $W_h$ of continuous piecewise linear functions defined with respect to this triangulation. Specifically, we partition the square into $N \times N$ smaller squares of size $h = 1/N$ and break each of the smaller squares into two triangles by connecting the lower left and upper right hand vertices. Functions in $W_h$ vanish on $\Gamma_D$ but not on $\Gamma_N$.

Instead of introducing a preconditioner for this example, we use $B_h = T_h$. Since the grid is regularly spaced, it is possible to compute the action of $T_h$ by using the discrete Sine Transform. Indeed, let $w_h = T_hf$ and let $\tilde{w}_h$ be the function defined on $\tilde{\Omega} \equiv [0,2] \times [0,1]$ resulting from an even extension of $w_h$ with respect to the line $x = 1$. Then, $\tilde{w}_h$ is the solution of

$$
\check{D}(\tilde{w}_h, \phi) = (\tilde{f}, \phi) \quad \text{for all } \phi \in \tilde{W}_h.
$$

Table 5.1: Convergence behavior for a smooth solution

Here \( \bar{D} \) denotes the inner product in \( H^1(\Omega) \), \( \bar{W}_h \) is the approximation subspace resulting from reflecting the mesh and \( \bar{f} \) is the even extension of \( f \). Functions in \( \bar{W}_h \) vanish on \( \partial\Omega \). Since the mesh is uniform, the discrete Sine Transform provides an algorithm for expanding solution vectors in terms of the discrete eigenvectors corresponding to the stiffness matrix for (5.2). The solution is readily obtained by multiplying by the inverse of the discrete eigenvalues and transforming back. The inverse transform is also a discrete Sine Transform. The cost of this evaluation is \( O(N^2 \log(N)) \) since the Sine Transform can be evaluated in terms of the Fast Fourier Transform.

For the first example, we consider a problem with smooth solution. Specifically, we take as a solution,

\[
u = x(y - y^2)\]

along with the corresponding right-hand-side function \( f \) and non-homogeneous oblique boundary condition

\[
\frac{\partial u}{\partial n} + \frac{\partial u}{\partial \mathbf{e}} = g \quad \text{on } \Gamma_N.
\]

Let \( U \) be the solution of (3.20). Table 5.1 gives the error \( u - U \) in the discrete \( L^2 \) and \( L^\infty \) norms as a function of \( h \). Note that the asymptotic convergence appears to be second order in both norms. This is better than predicted by the theory and only holds for smooth solutions.

Smooth solutions of (5.1) are somewhat artificial. In general, the solutions to the above problem fail to be in \( H^2(\Omega) \) because of singular behavior at the vertex \((1,1)\). We next illustrate the convergence behavior on a more realistic problem. Specifically, we set up a solution \( u \) of (5.1) which illustrates the typical singular behavior while resulting in right-hand-side data \( f \) in \( L^2(\Omega) \). Let \( \eta(r) \) be a \( C^2 \) function satisfying

\[
\eta(r) = \begin{cases} 
1 & \text{if } r \in [0, 1/4], \\
0 & \text{if } r > 1/2.
\end{cases}
\]

Table 5.2: Convergence behavior for a singular solution

We then define $u$ by

$$u(x) = r^{1/2} \sin(\phi/2) \eta(r)$$

where $(r, \phi)$ are the polar coordinates with origin at $(1,1)$. It is easy to see that $u$ satisfies (5.1) with $f = -\Delta u$ in $L^2(\Omega)$.

Table 5.2 gives the error $u - U$ in the discrete $L^2$ and $L^\infty$ norms as a function of $h$. As expected, the convergence rate is less than second order but somewhat better than first order for the $L^2$-norm of the error.
