Abstract
This paper addresses the well-known dispersion effect that mass lumping induces when solving transport-like equations. A simple anti-dispersion technique based on the lumped mass matrix is proposed. The method does not require any non-trivial matrix inversion and has the same anti-dispersive effects as the consistent mass matrix. A novel quasi-lumping technique for $P_2$ finite elements is introduced. Higher-order extensions of the method are also discussed.

1. Introduction

Lumping the mass matrix is a routine procedure in the finite element community when solving the heat equation, the wave equation and the time-dependent transport equation. This technique consists of replacing the consistent mass matrix by a diagonal surrogate usually referred to as the lumped mass matrix. This process avoids having to invoke sophisticated linear algebra arguments to invert the consistent mass matrix at each time step. The mantra in the literature dedicated to mass lumping is that mass lumping produces explicit algorithms for the transport and the wave equations that are algebra-free.

The lumped mass matrix is generally obtained by using a quadrature formula instead of exact integration. It is usually believed that lumping is a benign operation since it does not affect the overall accuracy of the method provided the quadrature is accurate enough. For instance, it is known that using quadrature formulas that are exact for $P_2$ polynomials is sufficient to preserve the overall accuracy of the Galerkin method when solving the wave equation or some eigenvalue problems on simplex meshes [1,7,12,11,20]. Although it is convenient numerically, it is well-known that lumping the mass matrix induces dispersion errors that have adverse effects when solving transport-like equations, see e.g. [5,6,14,22].

The objectives of the present work are as follows:

(i) We propose a simple correction technique based on the lumped mass matrix that does not involve sophisticated linear algebra and that has the same anti-dispersive effects as the consistent mass matrix. Although this correction technique relies on a matrix series, we show theoretically and numerically that only considering the first term in this series is enough to correct the dominating dispersion error.

(ii) We introduce a novel quasi-lumping technique for $P_2$ finite elements, where the new $P_2$ quasi-lumped mass matrix is triangular. We show also that the proposed mass correction technique is efficient when using this $P_2$ quasi-lumped mass matrix.

(iii) We investigate higher-order extensions of the correction method and demonstrate satisfactory results for the $P_3$ approximation.
To the best of our knowledge, the correction techniqued the qua-
sl- lumping technique for $P_2$ finite elements are original.

This paper is organized as follows. The anti-dispersive effects of the consistent $P_1$ mass matrix on the transport equation are ana-
yzed in Section 2. We focus in this section on the linear transport
equation in one space dimension. Most of the material therein is
standard. A mass correction technique based on the lumped mass
matrix is presented in Section 3. The method has the same alge-
braic complexity as when using the lumped mass matrix. It is also
proved for $P_1$ elements in one space dimension that using one cor-
tection term only is enough to obtain the same anti-dispersive ef-
fect as when using the consistent mass matrix. The mass correction
method is further evaluated numerically in two space dimension
on $P_1$ finite elements in Section 4. A new $P_2$ quasi-lumping tech-
nique is introduced in Section 5. To the best of our knowledge,
the $P_2$ quasi-lumping technique presented in Section 5.3 and Sec-
ction 5.4 and the mass correction technique introduced in Section 3
are original. Higher-order suboptimal variants of the method are
considered in Section 6. Conclusions are reported in Section 7.

2. One-dimensional heuristics

The objective of this section is to analyze in details the effects of
mass lumping in one space dimension for the linear transport
equation using piece-wise linear finite elements. The material
herein is certainly not new, see e.g. [6,14,17,22], but it is useful to
comprehend the rest of the paper. Let us consider the following
one-dimensional transport equation in the domain $\Omega = (a, b)
\partial_t u + \beta \partial_x u = 0, \quad u(x, 0) = u_0(x), \quad (x, t) \in (a, b) \times \mathbb{R}_+$, (2.1)
equipped with periodic boundary conditions. The velocity field $\beta$
assumed to be constant to simplify the presentation.

2.1. Galerkin linear approximation

Let us partition $\Omega = (a, b)$ into $N$ intervals $[x_i, x_{i+1}]$,
i = 0, . . . , N − 1. Let $h_i = |x_{i+1} − x_i|$ be the diameter of the cell
$[x_i, x_{i+1}]$. We introduce the family $\{\psi_i, \ldots, \psi_N\}$ composed of contin-
uous and piecewise linear Lagrange functions associated with the
nodes $\{x_0, \ldots, x_N\}$, and we define the $P_1$ finite element space
$X_0 = \{v \in C_0^0(\bar{\Omega}; R), \quad \|v\|_{X_0, h} \in P_1, \quad i = 0, \ldots, N − 1\}$
= span$\{\psi_0, \ldots, \psi_N\}$, (2.2)
where $C_0^0(\bar{\Omega}; R)$ denotes the space of the real-valued func-
tions that are periodic and continuous over $\bar{\Omega}$. Let $u_0$ be a reason-
able approximation of $u_0$, say the Lagrange interpolate or $L^2$-projection
thereof. An approximate solution to (2.1) is constructed by means
of the Galerkin technique. We seek $u \in C^0([0, T); X_0)$ so that
$u(0) = u_0$ and
\[
\int_{\Omega} (\partial_t u + \beta \partial_x u) v \, dx \, dt = 0, \quad \forall v \in X_0.
\]
(2.3)
The approximate solution $u(x, t)$ is expanded with respect to the ba-
sis $\{\psi_0, \ldots, \psi_N\}$ as follows: $u(x, t) = \sum_{i=0}^{N} u_i(t) \psi_i(x)$. A system of or-
dinary differential equations is obtained by testing (2.3) with the
members of the basis $\{\psi_0, \ldots, \psi_N\}$.

Upon testing (2.3) with $\psi_i$, $i = 0, \ldots, N$, the term involving the
time derivative gives
\[
\int_{\Omega} \partial_t u(x, t) \psi_i(x) \, dx \, dt = \sum_{j=0}^{N} M_{ij} \partial_t u_j(t),
\]
(2.4)
where the coefficients of the so-called mass matrix are
\[
M_{ij} := \int_{x_{i-1}}^{x_i} \psi_j(x) \psi_i(x) \, dx = \begin{cases}
\frac{1}{2} h_i & \text{if } j = i + 1 \\
\frac{1}{2} (h_i + h_{i+1}) & \text{if } j = i \\
0 & \text{otherwise}
\end{cases}
\]
(2.5)
with the convention that $h_{i+1} = h_i$ and $h_{N+1} = h_N$. The transport term in (2.3) is handled as follows:
\[
\int_{\Omega} \psi_i(x) \beta \partial_x u(x, t) \, dx = -\int_{x_{i-1}}^{x_i} \beta \partial_x u(x, t) \psi_i(x) \, dx
= \frac{\beta}{2} \left( u_{i-1}(t) + u_i(t) \right) - \frac{\beta}{2} \left( u_i(t) + u_{i+1}(t) \right),
\]
(2.6)
giving
\[
\int_{\Omega} \psi_i(x) \beta \partial_x u(x, t) \, dx = \beta \frac{1}{2} (u_{i-1}(t) - u_i(t)),
\]
(2.7)
with the convention $u_{i-1}(t) = u_{i-2}(t)$ and $u_{N+1}(t) = u_i(t)$.

Recalling that we are looking for a periodic solution, the above com-
putation shows that the vector $(u_0(t), \ldots, u_{N-1}(t))^T \in \mathbb{R}^N$ solves the
following system of ordinary differential equations:
\[
\sum_{j=0}^{N} M_{ij} \partial_t u_j(t) = -\beta \frac{1}{2} (u_i(t) - u_{i-1}(t)), \quad 0 \leq i, j < N,
\]
(2.8)
where $u_0(t) = u_N(t)$ and $u_{N-1}(t) = u_{i-1}(t)$. The above system can be
written in matrix form as follows:
\[
\begin{pmatrix}
M_0 & B & \\
B^T & -\beta & \cdot \\
0 & \cdot & \cdot
\end{pmatrix}
\begin{pmatrix}
u_0(t) \\
u_1(t) \\
... \\
u_{N-1}(t)
\end{pmatrix}
= \begin{pmatrix}u_0(t) \\
u_1(t) \\
... \\
u_{N-1}(t)
\end{pmatrix}
\]
(2.9)
with $U(t) := (u_0(t), \ldots, u_{N-1}(t))^T$, and the entries of $F$ are defined by
$F_i(U) := -\beta \left( u_i(t) - u_{i-1}(t) \right), 0 \leq i < N$, and where $M$ is the consistent
mass matrix defined in (2.5) taking into account the periodicity in
the first and last lines.

2.2. Dispersion and mass lumping

It is common in the literature to approximate (2.9) in time by
means of explicit time stepping. To avoid having to solve linear
systems involving the mass matrix at each time step, it also com-
mon to simplify (2.8) by lumping the mass matrix. Mass lumping
can be shown in one space dimension to be equivalent to approx-
imate the consistent mass matrix by using the following trapezoi-
dal quadrature rule:
\[
\int_{t}^{t+\Delta t} f(x) \, dx \approx (s − r) \frac{1}{2} (f(r) + f(s)).
\]
(2.10)
This quadrature is exact for linear polynomials. Using this qua-
drature, the mass matrix coefficients can be approximated as follows:
\[
\int_{x_{i-1}}^{x_i} \psi_i(x) \psi_j(x) \, dx \approx \frac{1}{2} \left( h_i + h_{i+1} \right) \delta_{ij} = M_{ij},
\]
(2.11)
where $\delta_{ij}$ is the Kronecker symbol. The so-called lumped mass ma-
trix $\tilde{M}$ thus computed is diagonal. Upon denoting
$\tilde{h}_i = \frac{1}{2} \left( h_i + h_{i+1} \right)$ and replacing the consistent mass matrix by
the lumped mass matrix, we obtain a new approximate form of
transport equation as follows:
\[
\partial_t u_i(t) + \beta \frac{\tilde{u}_{i-1} - \tilde{u}_i}{2\tilde{h}_i} = 0.
\]
(2.12)
The approximation thus constructed is second-order accurate. More
precisely, the consistency error of (2.12) is characterized by the
following.

Proposition 2.1. Provided the mesh is uniform, of mesh size $h$, the
dominating term in the consistency error of (2.12) at the grid points
$x_i$, $0 \leq i < N$ is dispersive and is equal to $\beta h_i \partial_x u(x_i, t)$.
Proof. Using \( x_{i+1} = x_i + h \) and upon using the Taylor expansion
\[
 u(x_i + h, t) = u(x_i) + h \partial_t u(x_i, t) + \frac{h^2}{2} \partial_{xx} u(x_i, t) + \frac{h^4}{24} \partial_{xxx} u(x_i, t) + \mathcal{O}(h^5),
\]
we infer that
\[
 \partial_t u(x_i, t) + \beta \frac{u(x_{i+1}, t) - u(x_{i-1}, t)}{2h} - \frac{h^2}{6} \partial_{xx} u(x_i, t) + \frac{h^4}{24} \partial_{xxx} u(x_i, t) + \mathcal{O}(h^5).
\]
This proves the statement of the proposition and proves also in passing that the equivalent limit equation is
\[
 \partial_t \tilde{u} + \beta \partial_t \tilde{u} + \frac{h^2}{6} \partial_{xx} \tilde{u} = 0,
\]
which is clearly dispersive. □

Remark 2.1. The key observation here is that the consistency error induced by mass lumping is second-order and dispersive.

Remark 2.2. The approximation (2.12) is exactly what a finite volume and a second-order finite difference approximation would give on a uniform mesh.

2.3. Anti-dispersive effect of the mass matrix

Let us now consider (2.8) where the mass matrix is not approximated, and let us redo the consistency analysis for this discrete system.

Proposition 2.2. Provided the mesh is uniform, of mesh size \( h \), the dominating term in the consistency error of (2.8) at the grid points \( (x_i)_{0 \leq i \leq N} \) is equal to \( \beta \frac{u_{i-1}}{2h} \partial_{xxx} u(x_i, t) \).

Proof. Using the definition of the mass matrix (2.5), the discrete system (2.8) can be re-written as follows:
\[
 \frac{1}{h} \sum_{j=1}^{1+1} M_{ij} \partial_t u_j = \partial_t u_i + \frac{1}{6} (\partial_t u_{i-1} - 2 \partial_t u_i + \partial_t u_{i+1}).
\]
Using Taylor expansions at \( x_i \) we obtain
\[
 \frac{1}{h} \sum_{j=1}^{1+1} M_{ij} \partial_t u_j(x_i) = \partial_t u(x_i, t) + \frac{h^2}{6} \partial_{xx} u(x_i, t) + \frac{h^4}{24} \partial_{xxx} u(x_i, t)
 + \mathcal{O}(h^5)
 = \partial_t u(x_i, t) - \beta \frac{h^2}{6} \partial_{xx} u(x_i, t) - \beta \frac{h^4}{24} \partial_{xxx} u(x_i, t)
 + \mathcal{O}(h^5).
\]
By proceeding again as in the proof of Proposition 2.1 and using \( u(x_i + h, t) = u(x_i) + h \partial_t u(x_i, t) + \frac{h^2}{2} \partial_{xx} u(x_i, t) + \frac{h^4}{24} \partial_{xxx} u(x_i, t) + \mathcal{O}(h^5) \), we infer that
\[
 \frac{1}{h} \sum_{j=1}^{1+1} M_{ij} \partial_t u_j(x_i) + \beta \frac{u(x_i+1, t) - u(x_i-1, t)}{2h}
 = \partial_t u(x_i, t) + \beta \partial_t u(x_i, t) - \beta \frac{1}{180} h^4 \partial_{xxx} u(x_i, t) + \mathcal{O}(h^5),
\]
thereby proving the statement. This also prove in passing that the equivalent limit equation is
\[
 \partial_t \tilde{u} + \beta \partial_t \tilde{u} - \beta \frac{h^4}{180} \partial_{xxx} \tilde{u} = 0,
\]

When comparing Propositions 2.1 and 2.2 we now understand that accounting properly for the mass matrix limits the dispersion error of the centered approximation.

Remark 2.3. It is remarkable that the result of Proposition 2.2 holds in higher-space dimension. For instance, it is shown in Appendix A that the result holds on quadrangular grids with \( Q_1 \) elements, independently of the transport direction.

Remark 2.4. The consistent mass matrix does not have anti-dispersive effect on the wave equation \( \partial_t \tilde{u} - c^2 \partial_{xx} \tilde{u} = 0 \), however, a simple computation as above shows that using \( \frac{1}{2} (M + \mathcal{M}) \) is the right combination to do the job with \( P_1 \) finite elements on uniform grids. See [5] and references therein for other details.

2.4. Fourier analysis

Fourier analysis is useful to evaluate numerical dispersion, and the purpose of this section is to revisit the statements of Propositions 2.1 and 2.2 from the Fourier analysis perspective. Let \( k \) be a real number and assume that \( u_0(x) = e^{i k x} \), \( \beta = -1 \), then the exact solution to (2.1) is \( u(x,t) = \Re (e^{i k (x - c t)}) \). Let us now compare this solution to what (2.8) and (2.12) give, respectively.

Proposition 2.3. If the initial data to (2.8) and (2.12) is \( \{ \omega e^{ikx} \}_{0 \leq i \leq N} \), the solution to (2.8) and (2.12) is \( \{ \omega e^{i k (x - c t)} \}_{0 \leq i \leq N} \) and \( \{ \omega e^{i k (x - c t - h \beta \tilde{u})} \}_{0 \leq i \leq N} \), respectively, where
\[
 c_1(k) = 3 \beta \frac{\sin(kh)}{k(2 + \cos(kh))}, \quad c_2(k) = \beta \frac{\sin(kh)}{kh}.
\]
Proof. This result is not new (see e.g. [14, p. 136]), but we give the proof for the sake of completeness. Let us assume that the solution to (2.8) is given by \( \{ \omega e^{i k (x - c t)} \}_{0 \leq i \leq N} \), where \( c_1(k) \) is yet to be determined. Then by inserting this expression into the following equivalent form of (2.8)
\[
 \partial_t u_i + \frac{1}{6} (\partial_t u_{i-1} - 2 \partial_t u_i + \partial_t u_{i+1} + \partial_t u_{i-1}) + \frac{u_{i-1} - u_{i+1}}{2h} = 0,
\]
we infer that the following must hold:
\[
 0 = -i k c_1(k) \left( 1 + \frac{1}{6} (e^{ik} - 2 + e^{-ik}) \right) + \beta \frac{1}{2h} (e^{ik} - e^{-ik})
 = -i k c_1(k) \left( 2 + \cos(kh) \right) + i \beta \frac{1}{h} \sin(kh),
\]
which is equivalent to the expression of \( c_1(k) \) in (2.16). The same argument gives \( c_2(k) \).

The graph of the phase velocities \( c_1(k)/\beta = \) and \( c_2(k)/\beta \) for \( k \in [0, \pi/h] \) are shown in Fig. 2.1. This figure shows that phase velocity \( c_2(k)/\beta \) is closer to the perfect value 1 than \( c_1(k)/\beta \), i.e., (2.8) transports the high frequencies better than (2.12), thereby confirming again that the consistent mass matrix has anti-dispersive properties. The anti-dispersive effect of the consistent mass matrix is illustrated numerically on the one-dimensional linear transport equation in Appendix B.1.

3. Mass matrix corrections

Since solving the mass matrix at each time step may be perceived as a drawback of the finite element method, we describe in this section a technique that has the same anti-dispersive effect as the consistent mass matrix but whose complexity is nearly the same as when using the lumped mass matrix.
3.1. An abstract result

The generic form of the system (2.9) can be re-written as follows:
\[ \partial_t U - M^{-1} F(U) = 0, \quad (3.1) \]
and our goal in this section is to approximate \( M^{-1} \) efficiently. To this end we set \( M = \overline{M} + M - \overline{M} \), where we assume that \( \overline{M} \) is easy to invert, e.g., \( \overline{M} \) can be the lumped mass matrix. At this point one may factorize \( \overline{M} \) on the left, right, or symmetrically as follows:
\[ M = \overline{M}(I + M^{-1}(M - \overline{M})), \quad (3.2) \]
\[ M = (I + (M - \overline{M})M^{-1})\overline{M}, \quad (3.3) \]
\[ M = \overline{M}^{-1/2}(I + \overline{M}^{-1/2}(M - \overline{M})\overline{M}^{-1/2})\overline{M}^{1/2}. \quad (3.4) \]

Note that the symmetric factorization is provided if \( \overline{M} \) is symmetric and non-negative, and if of interest only if \( \overline{M} \) is diagonal, since \( \overline{M}^{1/2} \) is easy to compute in this case. Depending on factorization which is chosen we introduce the following matrices:
\[ A_0 = \overline{M}^{-1}(M - \overline{M}), \quad A_1 = \overline{M}^{-1/2}(M - \overline{M})\overline{M}^{-1/2}, \quad \text{or} \quad A_i = (M - \overline{M})M^{-i}. \quad (3.5) \]

We then obtain the following three possible representations for \( M^{-1} \):
\[ M^{-1} = (I + A_0 + A_1^2 + \cdots)\overline{M}^{-1}, \quad (3.6) \]
\[ M^{-1} = \overline{M}^{-1/2}(I + A_0 + A_1^2 + \cdots)\overline{M}^{-1/2}, \quad (3.7) \]
\[ M^{-1} = \overline{M}^{-1/2}(I + A_0 + A_1^2 + \cdots)\overline{M}^{-1/2}. \quad (3.8) \]

Of course these representations are valid only if the series are convergent, which is the case if and only if the spectral radius of \( A \) is less than 1.

**Lemma 3.1.** The spectra of \( A_0, A_1 \) (provided \( \overline{M} \) is symmetric and non-negative) and \( A_i \) are identical.

**Proof.** That the spectra of \( A_0 \) and \( A_1 \) are identical is the consequence of the standard result that the spectra of \( \overline{C} \) and \( \overline{D} \) are identical for all square matrices \( C, D \). Let us now assume that \( \overline{M} \) is symmetric and non-negative, then \( A_0 \) is symmetric, thus diagonalizable. Let \( \lambda_i \) and \( V_i \) be the eigenvalues and eigenvectors of \( A_0 \), respectively. Then using the definition \( A_i V_i = \lambda_i^{i} V_i \) we infer that
\[ M^{-1/2} A_0 M^{-1/2} M^{-1/2} V_i = M^{-1/2} V_i \lambda_i, \]
which in turn implies \( A_0 M^{-1/2} V_i = M^{-1/2} V_i \lambda_i \), thereby proving that the spectra of \( A_0 \) and \( A_1 \) are identical. \( \square \)

One of the key results of this paper is that \( P_1 \) lumped mass matrix in one space dimension and in higher dimensions is such that the above series are convergent, and that using only one term in the series, i.e., \( 1 + A_i \), is enough to compensate exactly the dominating dispersive effects of mass lumping.

3.2. One-dimensional argumentation

We show in this section that using \( (1 + A)M^{-1} \) is enough to correct the dispersive effects of mass lumping in one space dimension with \( P_1 \) elements. Note that in one space dimension and with \( P_1 \) finite elements \( A_i = A_i = A \) when the mesh is uniform.

**Proposition 3.1.** Provided the mesh is uniform, of meshsize \( h \), the dominating term of the consistency error at the grid points \( \{x_i\} \cap \mathbb{N} \) is \( \mathcal{O}(h^3) \) when using only one correction in (3.6).

**Proof.** Observe that \( M = \mathcal{M} \) and \( A_i = I - h^{-1} M \). This implies that \( (1 + A)M^{-1} = h^{-1} (2I - h^{-1} M) \). The approximation equation is
\[ \partial_t u_i + \frac{\beta}{2h} \sum_{j=1}^{n} \left[ 2\delta_{ij} - h^{-1} M_{ij} \right] (u_{i+1} - u_{i-1}) = 0, \]
giving
\[ \partial_t u_i + \frac{\beta}{2h} \left( \frac{1}{6} (u_{i-2} - u_{i+2}) + \frac{4}{3} (u_{i+1} - u_{i-1}) \right) = 0. \]
Using Taylor expansions at \( x_i \), we obtain that
\[ \partial_t u(x_i, t) + \frac{\beta}{2h} (u(x_{i-1}, t) - u(x_{i+1}, t)) + \mathcal{O}(h^3), \]
which completes the proof. Note that this result is similar to what has been obtained in (2.14) when using the consistent mass matrix. \( \square \)

The above result is illustrated in Appendix B.2 in one space dimension.

4. Application to \( P_1 \) finite elements

We show in this section that the observations made in one space dimension generalize to two space dimensions. We restrict ourselves to two space dimensions for the sake of simplicity, but most of what is said hereafter generalizes to higher space dimensions.

4.1. The lumped \( P_1 \) mass matrix

Let \( \Omega \) be a two-dimensional polygonal domain and consider an affine finite element mesh \( \mathcal{T}_h \) of \( \Omega \) composed of simplices. Consider a cell in the mesh, \( K \in \mathcal{T}_h \), and let \( S_1, S_2, S_3 \) be the three vertices of \( K \) and \( \phi_1, \phi_2, \phi_3 \) be the associated local nodal shape functions. The local mass matrix \( M^K \) associated to \( K \) is defined to be
\[ M^K := \int_K \phi_i(x) \phi_j(x) \mathbf{d}x = ||\phi_i||^2 W \Phi, \quad (4.1) \]
where \( \{\phi_1, \phi_2, \phi_3\} \) is the canonical basis of \( \mathbb{R}^3 \) and the matrix \( W \) is given by
\[ W = \begin{bmatrix} 1 & \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & 1 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{2} & 1 \end{bmatrix}. \quad (4.2) \]
Once \( M^K \) is computed for all \( K \in \mathcal{T}_h \), the mass matrix \( M \) is obtained by the so-called assembling procedure.
The standard mass lumping process advocated in the literature consists of using the following approximate quadrature rule:

\[ \int_{\Omega} f(x) \, dx = [K(\phi_1) + \frac{1}{2} \phi_2)] \phi_i \, dx, \quad \forall f \in \mathcal{P}_1, \tag{4.3} \]

to approximate \( \int_{\Omega} \phi_i(x) \phi_j(x) \, dx \). The local lumped matrix \( \mathbf{M}^L \) obtained by this technique is

\[ \mathbf{M}^L := \int_{\Omega} \phi_i \phi_j \, dx \tag{4.4} \]

where the matrix \( \mathbf{W} \), computed by means of the above quadrature rule is

\[
\mathbf{W} = \begin{bmatrix}
0 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}.
\]

Of course, since \( \mathbf{W} \) is diagonal, \( \mathbf{M}^L \) is diagonal and the assembled matrix \( \mathbf{M} \) is also diagonal.

The popularity of the lumped \( \mathcal{P}_1 \) mass matrix, \( \mathbf{M} \), comes from the fact that it can be shown to be a satisfactory alternative of the consistent mass matrix, \( \mathbf{M} \), in terms of approximation and convergence rate, at least for the heat and the wave equation, [1,7,20]. That the matrix \( \mathbf{W} \) is indeed a good approximation of \( \mathbf{W} \) is also expressed in the following

**Proposition 4.1.** The three eigenvalues of \( \mathbf{W}^{-1}(\mathbf{W} - \mathbf{W}) \) are \( (0, \frac{1}{3}, \frac{2}{3}) \).

### 4.2. Numerical illustrations

We illustrate the efficiency of the correction algorithm in this section. We show in particular that using one term in the correction series is sufficient to remove the dominating dispersion error. Let us consider the scalar transport equation

\[ \partial_t u + \mathbf{b} \cdot \nabla u = 0, \quad u(x, 0) = u_0(x), \tag{4.6} \]

in the unit disk \( \Omega = \{(x, y) \in \mathbb{R}^2, \sqrt{x^2 + y^2} < 1\} \). The velocity field is a solid rotation of angular velocity \( 2\pi \), i.e., \( \mathbf{b} = 2\pi(-y, x) \). The initial field \( u_0 \) is defined by

\[ u_0(x) = \frac{1}{2} \left( 1 - \tanh \left( \frac{(x-x_0)^2 + y^2}{a^2} - 1 \right) \right), \quad x_0 = 0.4, \quad a = 0.3. \tag{4.7} \]

We solve (4.6) with the Galerkin method with \( \mathcal{P}_2 \) finite elements on a mesh composed of 6293 \( \mathcal{P}_1 \) nodes. The time stepping is done with the standard RK4 method (RK3 and RK4 techniques are known to be stable under a CFL condition for the linear transport equation, see e.g., [16]); this ensures that the error induced by the time approximation is small compared to the spatial error. The solution is computed at \( T = 2 \), i.e., after two revolutions.

The results are shown in Fig. 4.1. The solution obtained with mass lumping is shown in 4.1(a). The dispersive effect is clear and needs not be commented. We show in Fig. 4.1(b) and (c) the solutions obtained by replacing the inverse of the lumped mass matrix by \((1 + \mathbf{A})^{-1} \) and \((1 + \mathbf{A})^{-1} + \mathbf{A}^\dagger(M - \mathbf{M}) \), respectively, where \( \mathbf{A} = \mathbf{M}^{-1} \). The effect of applying only one correction to the lumped mass matrix is spectacular, the dispersive waves have completely disappeared.

We have verified in tests not reported here that the solution obtained with four corrections is visually indistinguishable from that obtained by inverting exactly the consistent mass matrix. To make this statement more precise, we solve the above linear transport problem on various grids \( (h = 0.1, 0.05, 0.025, 0.0125, 0.01) \) and compute the \( L^2 \)-norm of the error at \( T = 1 \). The convergence results are reported in Table 4.1. For all practical purposes, the errors obtained by using the consistent mass matrix and by applying four corrections to the lumped mass matrix are identical. This series of tests clearly shows that correcting the lumped mass matrix four times is enough to obtain results that cannot be distinguished from those computed with the consistent mass matrix.

Let us finish this section by justifying the convergence of the Neumann expansion in (3.6). This is done by evaluating the spectral radius of the mass correction.

**Proposition 4.2.** The spectral radius of \( \mathbf{A} := \mathbf{M}^{-1}(\mathbf{M} - \mathbf{M}) \) is less than \( \frac{1}{2} \).

**Proof.** Let \( (Y, \lambda) \) be an eigenpair of \( \mathbf{M}^{-1}(\mathbf{M} - \mathbf{M}) \), i.e., \( Y^T(\mathbf{M} - \mathbf{M})Y = \lambda Y^T \mathbf{M}Y \). Then, using the fact that the mesh is affine, we infer

\[ Y^T(\mathbf{M} - \mathbf{M})Y = \sum_{k \in \mathcal{T}_h} Y^T_k (\mathbf{M} - \mathbf{M}) Y_k \leq \sum_{k \in \mathcal{T}_h} Y^T_k ||\mathbf{W} - \mathbf{W}|| Y_k, \]

where \( Y_k \) is the vector of the three components of \( Y \) that are associated to the vertices of the triangle \( \mathcal{T}_h \) and where \( ||\cdot|| \) denotes the Euclidean norm. Owing to Proposition 4.1, we infer that \( ||\mathbf{W} - \mathbf{W}|| \leq \frac{1}{2} ||\mathbf{W}|| \), which turns implies

\[ Y^T(\mathbf{M} - \mathbf{M})Y = \sum_{k \in \mathcal{T}_h} Y^T_k ||\mathbf{W} - \mathbf{W}|| Y_k \leq \sum_{k \in \mathcal{T}_h} Y^T_k ||\mathbf{W}|| Y_k = \frac{3}{4} Y^T \mathbf{M} Y. \]

In conclusion, \( Y^T(\mathbf{M} - \mathbf{M})Y = ||\mathbf{W}|| Y_k \leq \frac{3}{4} Y^T \mathbf{M} Y \), which concludes the proof.

Table 4.2 shows the largest eigenvalue of \( A := \mathbf{M}^{-1}(\mathbf{M} - \mathbf{M}) \) on the five Delaunay grids used in the convergence tests above. This table confirm that the spectral radius of \( A \) is indeed uniformly bounded by 0.75.

### 5. \( \mathcal{P}_2 \) finite elements

We now extend the above considerations to higher-order finite elements. We particularly focus our attention in this section on the \( \mathcal{P}_2 \) mass matrix.

#### 5.1. Terminology

The terminology “mass lumping” comes from the operation that consists of replacing the consistent mass matrix by a diagonal matrix whose entry in row \( i \) is the sum of all the entries of the consistent mass matrix in row \( i \). When using Lagrange finite elements, this operation is equivalent to choosing an approximate quadrature based on the interpolation points to compute the diagonal surrogate. This statement is made more precise in the following.

**Proposition 5.1.** Mass lumping and using the interpolation points as quadrature points to approximate the mass matrix give the same diagonal matrix.

**Proof.** This result is standard, but we give the proof for completeness. Clearly, the proposition holds for the assembled matrices \( \mathbf{M} \) and \( \mathbf{M} \) if it holds for the local matrices \( \mathbf{M} \) and \( \mathbf{M} \). Let us then focus on the local matrices.

Let \( K \) be the reference finite element and let \( \hat{\mathbf{A}}_1, \ldots, \hat{\mathbf{A}}_l \) be the Lagrange nodes on \( K \) and \( \hat{\varphi}_1, \ldots, \hat{\varphi}_l \) be the corresponding nodal shape functions. The following quadrature rule holds...
In the remainder of this paper we are going to use approximate mass lumping in the sense of Proposition 5.1. We are nevertheless going to make an abuse of language by referring to these alternative approaches as quasi-lumping.

5.2. The \( \tilde{P}_k \) construction

The above mass lumping technique is known to work properly only for the \( P_1 \) finite element in the class of the simplicial finite elements with the Lagrange nodes equally distributed on a uniform lattice on the reference elements, see Section 4. For instance mass lumping fails for \( P_2 \) finite elements in two space dimensions. Although the argumentation is standard, let us recall why mass lumping fails for the \( P_2 \) finite elements. \( H^1 \)-conformity and elementary symmetry considerations impose that there is a unique choice for the Lagrange nodes of the \( P_2 \) finite element; this unique set of nodes is shown in Fig. 5.1. The interpolation points are the vertices \( \{S_i : S_j, S_k\} \) and the mid-edges \( \{M_1, M_2, M_3\} \).

The quadrature based on this set of nodes is the following:

\[
\int_{K} f(x) dx = \frac{|K|}{3} [f(M_1) + f(M_2) + f(M_3)], \quad \forall f \in P_2.
\]

By virtue of Proposition 5.1 it immediately follows that the lumped mass matrix is singular since the weights at the vertices are zero. A similar result holds in three space dimensions.

Following the work of [8], it is now well understood that the mass lumping method can be salvaged by selecting the Lagrange nodes on a non-uniform lattice on the reference element and by augmenting the polynomial space \( P_k \) with extra degrees of freedom so that the resulting augmented space \( \tilde{P}_k \) produces a quadrature with positive weights. For instance, it is shown in [4,9,10] that augmenting the polynomial space \( P_2 \) with \( \mathbb{P}_3 \) is suitable for this purpose, where \( h(x) = (\lambda_1(x) - \lambda_2(x) - \lambda_3(x)) \) is the bubble function and \( \lambda_1(x), \lambda_2(x), \lambda_3(x) \) are the barycentric coordinates over \( K \). The quadrature associated with this polynomial space is as follows:

\[
\int_{K} f(x) dx = \frac{|K|}{20} [f(S_1) + f(S_2) + f(S_3)] + \frac{2}{15} [f(M_1) + f(M_2) + f(M_3)] + \frac{9}{20} f(G), \quad \forall f \in P_4,
\]

where \( G \) is the barycenter of \( K \). Higher-order versions of these ideas are proposed in [4,9,13,19].

We propose in the next two sections two quasi-lumping techniques for \( P_2 \) finite elements that do not require the extra barycentric degree of freedom invoked by \( \tilde{P}_2 \).

**Fig. 4.1.** Mass matrix corrections on a 2D Delaunay triangulation. \( P_1 \) finite elements, \( h = 0.025 \) (6293 \( P_1 \) nodes), \( T = 2 \).
5.3. Construction of a diagonal \( P_2 \) quasi-lumped mass matrix

We present in this section a first attempt at quasi-lumping the mass matrix based on the standard Lagrange \( P_2 \) nodes, see Fig. 5.1, and using a diagonal matrix.

Again, the local mass matrix \( M^e \) is given by the expression

\[
M^e_{ij} := \int_K \phi_i(x) \phi_j(x) \, dx = |K| \delta_{ij} W^e,
\]

(5.5)

where \( \{\phi_1, \ldots, \phi_6\} \) is the canonical basis of \( \mathbb{R}^6 \) and the matrix \( W \) is given by

\[
W = 
\begin{bmatrix}
1 & -1/2 & -1/2 & 0 & 0 & 0 \\
-1/2 & 1 & -1/2 & 0 & 0 & 0 \\
-1/2 & -1/2 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1/2 & -1/2 & 0 \\
0 & 0 & 0 & -1/2 & 1/2 & 0 \\
0 & 0 & 0 & 0 & 0 & 1/2
\end{bmatrix}
\]

(5.6)

The coefficients of \( W \) are equal to \( |K|^{-1} \int_K \phi_i(x) \phi_j(x) \, dx \) for \( i, j \leq 6 \), where \( \phi_1, \ldots, \phi_6 \) are the local nodal shape functions. Since we have seen above that (5.3) is the only possible quadrature that is exact for \( P_2 \) polynomials, we propose to lower our expectations by constructing a convex combination between (4.3) and (5.3) as follows:

\[
\int_K \phi_i(x) \, dx = \gamma \frac{|K|}{3} (f(S_1) + f(S_2) + f(S_3)) + (1 - \gamma) \left( \frac{|K|}{3} f(M_1) + f(M_2) + f(M_3) \right)
\]

(5.7)

This gives a family of integration rules parameterized by \( \gamma \) that are exact only in \( P_1 \), for all \( \gamma \in (0, 1) \). Since there are polynomials in \( P_2 \) that are not integrated exactly with these rules, this choice certainly forbids any hope that the resulting method can be optimal in terms of approximation, but we nevertheless persist in this direction. The quasi-lumped local mass matrix that results from this strategy is the following:

\[
\overline{M}^e_{ij} := |K| \delta_{ij} \overline{W}^e,
\]

(5.8)

where

\[
\overline{W} := \begin{bmatrix}
\frac{1}{2} & 0 & 0 \\
0 & \frac{1}{2} & 0 \\
0 & 0 & 1
\end{bmatrix}
\]

(5.9)

and

\[
[l_1] := \begin{bmatrix}
0 & 0 & 0 & \gamma & \delta & \delta \\
0 & 0 & \gamma & \delta & \delta & 0 \\
0 & 0 & 0 & \beta & 0 & 0 \\
0 & 0 & 0 & 0 & \beta & 0 \\
0 & 0 & 0 & 0 & 0 & \beta
\end{bmatrix}
\]

(5.11)

and with

\[
U^T := (u(S_1), u(S_2), u(S_3), u(M_1), u(M_2), u(M_3))
\]

(5.12)

\[
V^T := (v(S_1), v(S_2), v(S_3), v(M_1), v(M_2), v(M_3))
\]

(5.13)

We now try to make this formula as accurate as possible. Let \( \phi_1, \phi_2, \phi_3 \) be the \( P_2 \) nodal shape functions associated with the vertices \( S_1, S_2, S_3 \), and \( \phi_4, \phi_5, \phi_6 \) be the nodal shape functions associated with the mid-edges \( M_1, M_2, M_3 \).

5.4. Construction of a triangular \( P_2 \) quasi-lumped mass matrix

Since it does not seem to be possible to construct a diagonal \( P_2 \) mass matrix with optimal convergence properties, see §5.3, we propose to consider the next best alternative which is to construct a triangular approximate mass matrix. Recall that triangular matrices are as easy to invert as diagonal matrices. This possibility has never been explored yet, to the best of our knowledge. We propose to consider the following non-symmetric bilinear quadrature rule

\[
\int_K u(x) v(x) \, dx \approx |K| \overline{U}^T \overline{W} \overline{V},
\]

(5.10)

where the matrix \( \overline{W} \) is defined by

\[
U := \begin{bmatrix}
\alpha & 0 & 0 & \gamma & \delta & \delta \\
0 & \alpha & 0 & \gamma & \delta & \delta \\
0 & 0 & \alpha & \gamma & \delta & \delta \\
0 & 0 & 0 & \beta & 0 & 0 \\
0 & 0 & 0 & 0 & \beta & 0 \\
0 & 0 & 0 & 0 & 0 & \beta
\end{bmatrix}
\]

and

\[
\overline{W} := \begin{bmatrix}
|K|^{-1} \overline{W} \overline{W}^T
\end{bmatrix}
\]

(5.11)

Table 5.1

\begin{tabular}{|c|c|c|c|}
\hline
\( h \) & Consist. mass & Var. corrections & 4 Corrections \\
\hline
0.2 & 5.05E-2 & 5.53E-2 & 2 & 3.84E-2 \\
0.1 & 1.52E-2 & 1.22E-2 & 4 & 1.22E-2 \\
0.05 & 2.67E-3 & 2.77E-3 & 6 & 4.96E-3 \\
0.025 & 5.99E-4 & 5.86E-4 & 8 & 3.57E-3 \\
0.0125 & 1.44E-4 & 1.48E-4 & 10 & 3.44E-3 \\
\hline
\end{tabular}

In conclusion, although the proposed quasi-lumped mass matrix does not give an optimally convergent method when corrected a fixed number of times, we claim that the matrix \( M \) is nevertheless a good preconditioner of \( M \) and can certainly be used as such within any Krylov-based iterative technique. This claim is confirmed by Table 5.1 where we report the condition number of \( M^{-1} \) as a function of the mesh size \( h \) for the five grids used in the above convergence tests and for two values of \( \gamma \).
Lemma 5.1. The formula (5.10) is exact for all 
\( (u, v) \in P_2 \times P_0 \cup P_0 \times P_1 \) provided the following holds:

\[
\alpha + \gamma + 2\delta = 0, \quad \beta = \frac{1}{3}, \quad \forall \gamma, \delta \in \mathbb{R}.
\]  
(5.14)

(i) (5.10) is also exact for all \( (u, v) \in \text{span}(\phi_1, \phi_2, \phi_3) \times P_1 \) if (5.14) holds and

\[
\delta + \gamma = -\frac{1}{30}, \quad \forall \gamma \in \mathbb{R}.
\]  
(5.15)

(ii) (5.10) is exact for all \( (u, v) \in P_1 \times P_1 \) if (5.14) holds and

\[
\alpha + \gamma = 0, \quad \forall \gamma \in \mathbb{R}.
\]  
(5.16)

Proof.

(1) The condition \( \int_K \phi_i(x)dx = 0, i = 1, 2, 3 \) implies \( \alpha + \gamma + 2\delta = 0 \). The condition \( \int_K \phi_i(x)dx = \frac{1}{2K}, i = 4, 5, 6 \) implies \( \beta = \frac{1}{2} \). In conclusion (5.10) holds for all \( (u, v) \in P_2 \times P_0 \) provided \( \alpha + \gamma + 2\delta = 0 \) and \( \beta = \frac{1}{3} \). Moreover one easily verifies that \( \int_K 1 \lambda_i(x)dx = \frac{1}{2K} \) is computed exactly if \( \alpha + \beta + \gamma + 2\delta = \frac{4}{3} \), which with \( \beta = \frac{1}{2} \) gives again \( \alpha + \gamma + 2\delta = 0 \). This implies that (5.10) holds also for all \( (u, v) \in P_2 \times P_1 \). Note that these identities hold for the (singular) lumped mass matrix for which \( \alpha = \gamma = \delta = 0 \) and \( \beta = \frac{1}{3} \).

(2) The condition \( \int_K \phi_i(x)\lambda_i(x)dx = \frac{1}{3K}, i = 1, 2, 3 \) implies \( \alpha + \gamma + 2\delta = 0 \). In conclusion we have

\[
\alpha + \gamma + 2\delta = 0, \quad \alpha + \gamma = 0.
\]  
(5.15)

which is clearly equivalent to (5.14) and (5.15). Let \( i \in \{1, 2, 3\} \) and let \( \{j_1, j_2\} = \{1, 2, 3\} \setminus \{i\} \), then let us show that (5.10) evaluates exactly \( \int_K \phi_i(x)\lambda_{j_1}(x)dx \) and \( \int_K \phi_i(x)\lambda_{j_2}(x)dx \), which will conclude the proof of (i). Since the symmetries of the triangle \( K \) imply that \( \int_K \phi_i(x)\lambda_{j_1}(x)dx \) and \( \int_K \phi_i(x)\lambda_{j_2}(x)dx \) have

\[
\int_K \phi_i(x)\lambda_i(x)dx = \frac{1}{2} \int_K \phi_i(x)(\lambda_i(x) + \lambda_0(x))dx
\]

\[
= \frac{1}{2} \int_K \phi_i(x)(\lambda_i(x) + \lambda_1(x) + \lambda_2(x)dx - \frac{1}{2}
\]

\[
\int_K \phi_i(x)\lambda_i(x)dx = -\frac{1}{2} \int_K \phi_i(x)\lambda_i(x)dx.
\]

The conclusion follows readily owing to the fact that (5.10) satisfies all the symmetries used above and (5.10) evaluates exactly \( \int_K \phi_i(x)\lambda_j(x)dx \), \( i, j = 1, 2, 3 \).

(3) The proof of (ii) is similar. We observe first that (5.10) evaluates exactly \( \int_K \lambda_i(x)\lambda_j(x)dx \), \( i \in \{1, 2, 3\} \) provided

\[
\alpha + \gamma + \frac{1}{2} \beta = \frac{1}{6},
\]  
which together with the results of step (1) imply (5.14)–(5.16). Proving then that (5.10) evaluates exactly \( \int_K \lambda_i(x)\lambda_j(x)dx \) for \( j = \{1, 2, 3\} \setminus \{i\} \) can be done by using the symmetry properties of the quadrature as above. □

We now have two families of bilinear integration rules parameterized by \( \gamma \). Our goal is to use \( \mathcal{W} \) to approximate the matrix \( W \) defined in (5.6). We expect \( \mathcal{W} \) to be a good approximation of \( W \) if the spectral radius of \( \mathcal{W}^{-1} (\mathcal{W} - W) \) is smaller than 1. We show in Fig. 5.3 the spectral radius of \( \mathcal{W}^{-1} (\mathcal{W} - W) \) as a function of \( \gamma \) in the range \(-0.06 \leq \gamma \leq 0.01 \) for the integration rule defined by (5.14)–(5.15). The minimum is reached for \( \gamma \approx -\frac{1}{2} \) and the range \( \gamma \in [-0.042, -0.03] \) is acceptable. The particular value \( \gamma = -\frac{1}{2} \) has the advantage of simplifying the expression of \( \mathcal{W} \) since \( \delta = 0 \) for this value. We have found numerically that indeed the choice \( \gamma = -\frac{1}{2} \) works very well. We show in Fig. 5.3 the spectral radius of \( \mathcal{W}^{-1} (\mathcal{W} - W) \) as a function of \( \gamma \) in the range \( 0.015 \leq \gamma \leq 0.15 \) for the integration rule defined in (5.14)–(5.16). The minimum is reached for \( \gamma \approx \frac{1}{2} \) and the range \( \gamma \in [0.03, 0.07] \) is acceptable. We have found numerically that the pair \( \gamma = \frac{1}{2} \) works well for the integration rule (5.14)–(5.16).

Another important property to consider is to make sure that the quasi-lumped mass matrix is definite positive. This property holds as soon as the elementary matrix \( \mathcal{W} \) is definite positive. We verify that \( \mathcal{W} \) is definite positive by inspecting the smallest eigenvalue of \( \frac{1}{2} (\mathcal{W} + \mathcal{W}^T) \).

**Fig. 5.3.** Spectral radius of \( \mathcal{W}^{-1} (\mathcal{W} - W) \) as a function of \( \gamma \).
Remark 5.1. The mass matrix $\mathbb{M}$ preserves the block structure of the local mass matrices $\mathbb{M}_i$. For instance $\mathbb{M}_i$ is upper triangular if the vertices of the mesh are enumerated before the mid-edges.

Remark 5.2. The idea of using non-diagonal matrices to represent a quadrature rule can be traced back to [24, p. 5] and [18, (A.2)]. The novelty of the technique presented here is that we are using a triangular matrix to represent a quadrature rule involving the product of two functions. The resulting bilinear form is obviously not a scalar product.

Remark 5.3. Instead of considering the bilinear quadrature rule defined by (5.11), one may think of using the transpose of the matrix $\mathbb{W}$ thus giving a lower triangular quadrature rule. The counterpart of Lemma 5.1 follows immediately by permuting the polynomial spaces. One can then define another quasi-lumped mass matrix. This leads to two quasi-lumped matrices, say $\mathbb{M}_1$ and $\mathbb{M}_2$, where subscripts $1$ and $2$ are for lower or upper triangular. Let us then define the matrix $\mathbb{M} = (\frac{1}{2}\mathbb{M}_1^{-1} + \frac{1}{2}\mathbb{M}_2^{-1})^{-1}$. This new matrix $\mathbb{M}$ is clearly symmetric and can be used as a quasi-lumped mass matrix: the matrix vector product $\mathbb{M} y$ is realized by solving $\mathbb{M}_1 y = y$ and $\mathbb{M}_2 y = y$ and by setting $\mathbb{M} y = \frac{1}{2} (z_1 + z_2)$. The resulting algorithm is of course a little more time consuming, but the quasi-lumped mass matrix is now symmetric. This route has been investigated, but the results are somewhat disappointing. It seems that $\mathbb{M}_i$ is not nearly as effective as $\mathbb{M}_i$ when applying the dispersion correction formula with one term only. The two matrices give similar results after four corrections though. This phenomenon is not yet well understood. We conjecture that it is important to associate the largest polynomial space with the test functions in the quadrature rule (5.11); the quadrature associated with $\mathbb{M}_i$ is exact in $\mathbb{P}_0 \times \mathbb{P}_2$, whereas the quadrature associated with $\mathbb{M}_i$ is exact in $\mathbb{P}_2 \times \mathbb{P}_0$. Note finally that there is no local counterpart to the matrix $\mathbb{M} = (\frac{1}{2}\mathbb{M}_1^{-1} + \frac{1}{2}\mathbb{M}_2^{-1})^{-1}$ that defines a bilinear quadrature with properties similar to those mentioned in Lemma 5.1.

5.5. Numerical illustrations/Galerkin

We illustrate the efficiency of the construction proposed above by testing it on the linear transport equations Eq. (4.6) and (4.7) with the quadrature rule (5.14) and (5.15) using $\gamma = -\frac{1}{10}$ (i.e., $\alpha = \frac{3}{5}, \beta = \frac{1}{5}, \delta = 0$). Note in passing that the value $\gamma = -\frac{1}{10}$ is such that the three smallest eigenvalues of $\frac{1}{2}(\mathbb{W} + \mathbb{W}^T)$ are equal (see (5.17)). In this case we have

$$\mathbb{W} = \begin{bmatrix} \frac{4}{9} I \frac{1}{9} I \\ 0 & \frac{1}{9} I \end{bmatrix}. \quad (5.19)$$

The space approximation is done by using the Galerkin method on a mesh composed of 6293 $P_1$ nodes. The time stepping is done with the standard RK4 method to ascertain that the error in time is negligible with respect to the spatial error. The solution is computed at $T = 2$, i.e., after two revolutions. The results are shown in Fig. 5.4. The solution obtained with quasi-lumping is shown in Fig. 5.4(a). The dispersive effect associated with quasi-lumping is clear. We show in Fig. 5.4(b) and (c) the solutions obtained by replacing the inverse of the quasi-lumped mass matrix by $(1 + A)\mathbb{M}_1^{-1}$ and $(1 + A + A^2 + A^3)\mathbb{M}_2^{-1}$, respectively, where $A := (\mathbb{M}^{-1} - \mathbb{M})$. The conclusion is the same as for $P_1$ finite elements: Applying one correction to the quasi-lumped mass matrix is enough to correct the dispersion effect.

We finish this section by performing convergence tests on the linear transport problem (4.6) and (4.7). The space approximation is done by using the Galerkin method on various grids ($h = 0.2, 0.1, 0.05, 0.025, 0.0125$). The time stepping is done with RK4 with CFL = 0.7. The $L^2$-norm of the error is computed at $T = 1$. The results are reported in Table 5.3. It is remarkable that the technique using the uncorrected quasi-lumped mass matrix is second-order convergent. To the best of our knowledge, the technique presented here is the first convergent quasi-lumping technique for $P_2$ finite elements using only the standard Lagrangian nodes. It is also remarkable that for all practical purposes, the results obtained by using the consistent mass matrix and by applying four mass corrections to the quasi-lumped mass matrix are identical. This test confirms the observations already made with $P_1$ finite elements.

5.6. Numerical illustrations/Galerkin + stabilization

Since it is known that the Galerkin method is suboptimal for linear first-order PDE's, we now investigate the performance of the mass correction when used jointly with stabilization techniques.

We consider first the so-called edge stabilization technique [3]. Edge stabilization consists of augmenting the Galerkin formulation with a penalty term acting on the jump of the normal derivative of the unknown across all the internal faces of the mesh. Upon denoting $X_h$ the finite element space, the edge stabilization technique consists of seeking $u \in C^l(\Omega \setminus \{0\}, X_h)$ so that

$$\int_{\partial \Omega} (\partial_n u + \beta \cdot \nabla u) \cdot dx + \sum_{F \in \mathcal{F}_h} \frac{h_F}{\eta} \|\partial_n u\|_{L^2(F)} \int_F \|\partial_n v\|_{L^2(F)} dx = 0, \quad \forall v \in X_h, \quad (5.20)$$

where $\mathcal{F}_h$ is the collection of the internal faces, $h_F$ is the diameter of $F$, and $\eta$ is the union of the two elements sharing the interface $F$. The coefficient $\gamma$ is user-dependent; we have chosen $\gamma = 0.01$ in the computations reported below. The time stepping is again explicit and done using RK4. The edge stabilization bilinear form is made explicit. The resulting scheme is known to be stable under the usual CFL condition in [2]. We used CFL = 0.7 in the computations reported in Table 5.4. By comparing Tables 5.3 and 5.4, we observe that, as expected, the edge-stabilized technique is more accurate than the Galerkin technique. The results from Table 5.4 show that the technique with the quasi-lumped mass matrix corrected four times has roughly the same convergence rate as the technique using the consistent mass matrix.

We now consider the so-called entropy viscosity technique introduced in [15]. The method consists of adding a nonlinear dissipation to the Galerkin formulation to stabilize the method:

\(\text{Proposition 5.2.}\)

(i) With the choice of parameters (5.14)–(5.15), the smallest eigenvalues of $\frac{1}{2}(\mathbb{W} + \mathbb{W}^T)$ is

$$\min \left\{ \frac{1}{2} \sqrt{17 - 90 \gamma + 450 \gamma^2}, \frac{1}{2} \sqrt{65 - 360 \gamma + 4500 \gamma^2} \right\}. \quad (5.17)$$

(ii) With the choice of parameters (5.14)–(5.16), the smallest eigenvalues of $\frac{1}{2}(\mathbb{W} + \mathbb{W}^T)$ is

$$\min \left\{ \frac{1}{2} \sqrt{17 - 90 \gamma + 450 \gamma^2}, \frac{1}{2} \sqrt{65 - 360 \gamma + 4500 \gamma^2} \right\}. \quad (5.18)$$

One can verify that matrix $\mathbb{W}$ is definite positive for the two choices (5.14) and (5.15) and (5.14)–(5.16) in the ranges considered above, $\gamma \in [-0.042, -0.03]$ and $\gamma \in [0.03, 0.07]$, respectively.
We are going to restrict ourselves to simplicial Lagrange finite elements in two space dimensions. Furthermore we have verified numerically that the spectral radius of the local matrix $W_k$ is less than $157$ (i.e., $\alpha = 0.2$, $\beta = 1$, $\delta = -\frac{1}{5}$). The performance of the method is similar to what has been described above. We do not report these tests here for the sake of brevity.

The tests shown in this section confirm that the mass correction method is robust with respect to both the edge stabilization and the entropy viscosity technique.

6. $P_N$ extensions

We finish this paper by exploring mass lumping for higher-order simplicial Lagrange finite elements in two space dimensions. We are going to restrict ourselves to $P_N$ finite elements, $N \geq 3$, and investigate whether it is possible to find lattices on the reference simplex that give lumped mass matrices with positive weights and determine whether the mass matrix correction from Section 3 can be applied. Of course the quadrature associated with mass lumping in $P_N$ is exact, which is suboptimal since quadratures must be exact in $P_{2N-2}$ to yield optimal error estimates in the energy norm [1,7,20,11].

6.1. $P_3$ approximation

We begin with the $P_3$ approximation. As generally advocated in the spectral element literature, the interpolation points for $P_3$ Lagrange finite elements must be the images, by appropriate mappings, of the four one-dimensional Gauss–Lobatto Legendre points $\{-1, -1/\sqrt{5}, 1/\sqrt{5}, 1\}$ on the edges of the triangle and the center of gravity of the triangle. The quadrature associated with these points is exact in $P_3$ only, but since all the weights are positive (suboptimal) mass lumping is possible for this finite element. Furthermore we have verified numerically that the spectral radius of the local matrix $W \quad W - W$ approximately equals $0.702 < 1$, thereby confirming that the mass matrix correction algorithm proposed in Section 3 is convergent.

Let us now illustrate the mass correction algorithm on the two-dimensional transport problem defined in Section 4.2. We have performed computations on four grids ($h = 0.157, 0.0753, 0.0575, 0.039$) with the consistent mass matrix.
the lumped mass matrix, and the lumped mass matrix corrected up to eight times. The computations have been done with the symmetric form of the mass correction matrix $A$, see (3.7), but this particular choice does not affect the spectral radius of $A$ as shown in Lemma 3.1. The results are reported in Table 6.1.

As can be observed in Table 6.1, the convergence rate obtained with the standard mass lumping is less than second-order (as expected), whereas it is close to fourth-order with the consistent mass matrix. One observes significant improvements with the mass correction algorithm. This is remarkable since the quadrature based on the interpolation points is exact in $P_1$ and is not in $P_{2N−1,2−4}$. Moreover, as already observed for the $P_2$ approximation, the mass correction algorithm gives slightly better accuracy than when using the consistent mass matrix when the number of mass corrections is larger enough. This seems to indicate that the convergence of the Neumann series (3.7) always occurs from below.

### 6.2. Higher-order variants

Let us now consider higher-order polynomials, i.e., $N \in \{4, 5, 6\}$. For $N \in \{4, 5\}$ we consider the interpolation points given by the “warp & blend” technique from [23] and, for $N = 6$, we use the so-called Feke points. The list of the Feke points in the reference triangle for $N \in \{3, 6, \ldots , 18\}$ can be found in [21]. For both these families, the interpolation nodes coincide with the Gauss–Lobatto–Legendre points on the edges of the reference triangle. The Lebesgue constant for both these families is small; for instance, it is less than 10 for polynomial of degrees at 12.

The first difficulty we encounter when computing the weights of the quadrature associated with the warp & blend points is that the weights at the vertices are negative for $N = 4$. The second problem is that the spectral radius of the local matrix $A$ grows with $N$ and is larger than 1 for $N \geq 4$ as shown in Table 6.2 for $N \in \{3, 4, 5, 6\}$.

The above negative results show that standard mass-lumping fails for $N > 3$ in two space dimensions for standard Lagrange elements. This situation can be fixed by using the augmented spaces $P_N$ mentioned in Section 5.2. This idea has been shown to work up to $N = 6$ in two space dimensions and up to $N = 4$ in three space dimensions in [4]. We have that however the quasi-lumping technique that we developed for $P_2$ finite elements in Section 5.4 can be extended to higher-order polynomial degree. We think in particular that it should be possible in principle to construct triangular quasi-lumped mass matrices as alternatives to the $P_N$ construction.

### 7. Conclusions

A new mass correction technique has been introduced to correct the dispersion error of mass lumping. The method has been shown to have the same anti-dispersive effect as when working with the consistent mass matrix. Two quasi-lumping techniques for $P_2$ finite elements have been introduced. The $P_2$ quasi-lumping technique based on the idea of using a triangular lumped mass matrix, as presented in Section 5.4, is new to the best of our knowledge. The mass correction technique introduced in Section 3 has been shown to perform very well with $P_1$ lumping and $P_2$ quasi-lumping. It seems that for these two elements using only one correction term only is enough to remove the dispersion error. We have verified that, although suboptimal, satisfactory results can also be obtained for the $P_3$ approximation.

The idea of applying the mass matrix corrections and using triangular quasi-lumped mass matrices could be extended to higher-order finite elements. These venues will be explored in future works.

### Appendix A. Anti-dispersive effect of the $Q_1$-mass matrix on 2D Cartesian grids

Consider the two-dimensional transport equation:

$$\partial_t u + \beta \cdot \nabla u = 0,$$

with constant velocity field $\beta = (\beta_x, \beta_y)$. Consider a Cartesian grid with mesh sizes $h_x$ and $h_y$ in $x$- and $y$-directions, respectively.

**Proposition A.1.** The dominating term in the consistency error of the $Q_1$ Galerkin approximation is $O(h_x^4 + h_y^4)$ at the grid points $(x_j, y_j)$.

**Proof.** The test functions are the tensor products of one-dimensional functions, say $\psi_i(x)\psi_j(y)$, and the $Q_1$ Galerkin approximation is represented as follows:

$$u(x, y, t) = \sum_{i} \sum_{j} u_{ij}(t) \psi_i(x)\psi_j(y).$$

Applying twice the Simpson quadrature rule, the term involving the time derivative becomes

$$\int_{x_{j-1}}^{x_{j+1}} \int_{y_{i-1}}^{y_{i+1}} \partial_t u \psi_i \psi_j \, dx \, dy = h_y h_x \partial_t \left( \int_{x_{j-1}}^{x_{j+1}} \int_{y_{i-1}}^{y_{i+1}} \frac{4}{3} u_{ij} + \frac{1}{3} (u_{i\pm 1,j} + u_{i,j\pm 1}) + \frac{1}{56} u_{i\pm 1,j\pm 1} \right),$$

where the notation $u_{i\pm 1,j}$ stands for $u_{i+1,j} + u_{i-1,j}$ and $u_{i,j\pm 1}$ stands for $u_{i,j+1} + u_{i,j-1} + u_{i-1,j+1} + u_{i-1,j-1}$, etc. Similarly, for the transport term we obtain:

$$\int_{x_{j-1}}^{x_{j+1}} \int_{y_{i-1}}^{y_{i+1}} \beta \cdot \nabla u \psi_i \psi_j \, dx \, dy = h_y h_x \left( \int_{x_{j-1}}^{x_{j+1}} \int_{y_{i-1}}^{y_{i+1}} \frac{1}{3} (u_{i,j+1} + u_{i,j-1}) + \frac{1}{12} (u_{i,j+1} - u_{i,j-1}) \right) + h_x h_y \left( \int_{x_{j-1}}^{x_{j+1}} \int_{y_{i-1}}^{y_{i+1}} \frac{1}{3} (u_{i+1,j} - u_{i-1,j}) + \frac{1}{12} (u_{i+1,j+1} + u_{i+1,j-1}) \right).$$

After inserting the exact solution, $u$, in the $Q_1$ Galerkin approximation of the transport equation, using Taylor expansions, and dividing by $h_y h_x$, we obtain:
\[ \frac{1}{h_x h_y} \int_{S_i} \left( \partial_t u_{ij} + \beta \cdot \nabla u_{ij} \right) \psi_i(x) \psi_j(y) \, dx \, dy = \alpha \left( u_{ij} + \frac{h_y^2}{6} \partial_{x} u_{ij} + \frac{h_y^2}{6} \partial_{y} u_{ij} \right) + \beta_y \left( \partial_t u_{ij} + \frac{h_y^2}{6} \partial_{x} u_{ij} + \frac{h_y^2}{6} \partial_{y} u_{ij} \right) \beta_x \]

where \( S_i = [x_{i-1}, x_i] \times [y_{j-1}, y_j] \) and \( u_{ij} := u(x_i, y_j) \). Taking into account that \( \partial_t u(x_i, y_j, t) = -\beta_x \partial_x u(x_i, y_j, t) - \beta_y \partial_y u(x_i, y_j, t) \), one observes that the consistency error is of order 4.

The above proposition shows that using the consistent matrix has an anti-dispersive effect for the 2D transport equation. One may conjecture that such a result holds in any dimension.

**Appendix B. One-dimensional numerical illustrations**

### B.1. Dispersive effects of mass lumping

We illustrate here the anti-dispersive effect of the consistent mass matrix in one space dimension. We show in Fig. B.1(a) and (b) the Galerkin solution to the transport equation \( \partial_t u + \partial_x u = 0 \) over the interval \( \Omega = (0, 1) \) with periodic boundary conditions and initial data \( u(x, 0) = \sin(2\pi x) \). The solution is computed at \( T = 100 \), i.e., 100 periods, on a uniform mesh composed of 100 \( \mathbb{P}_1 \) cells. The time stepping is done using the standard explicit forth-order Runge Kutta (RK4) method so that the error induced by the time approximation is negligible with respect to the spatial error. The CFL number is 0.7. We show in Fig. B.1(c) and (d) the Galerkin solution with the initial data \( u(x, 0) = 1 \) if \( 0.4 < x < 0.7 \) and \( u(x, 0) = 0 \) otherwise. The solution is computed at \( T = 1 \). The solutions shown in Fig. B.1(a) and (c) are computed with the lumped mass matrix, and those shown in Fig. B.1(b) and (d) are computed with the consistent mass matrix. The anti-dispersive effects of the consistent mass matrix are clearly visible on these two examples.

Since the dispersion analysis has been done assuming that the mesh is uniform, it is not clear a priori that the anti-dispersive effects of the mass matrix are robust with respect to mesh non-uniformity. This issue can be explored numerically by repeating the above numerical experiments on non-uniform meshes. The results are shown in Fig. B.2. The mesh is composed of 100 cells with random size and the anisotropy factor is 3, that is to say the size ratio between two neighboring cells is at most 3. These experiments show that mesh non-uniformity does no have a notable influence on the anti-dispersive effects of the consistent mass matrix, and the conclusions of the dispersion analysis hold when the mesh is moderately non-uniform.

### B.2. Numerical illustrations of the correction technique

We illustrate numerically the correction technique introduced in Section 3 in one space dimension with \( \mathbb{P}_1 \) finite elements. We show in Fig. B.3 the effects of replacing the inverse of the lumped mass matrix by (3.6). The setting is the same as in Section B.1 and the initial data is the smooth sine function. We show in Fig. B.3(a) the Galerkin solution using the lumped mass matrix on a random mesh composed of 100 cells at \( T = 100 \). The solutions shown in Fig. B.3(c) and (d) have been obtained by replacing \( M^{-1} \) by \( (1 + A)M^{-1} \) and \( (1 + A + A^2 + A^3)M^{-1} \), respectively. Fig. B.3(a) clearly illustrates the dispersion effect of mass lumping; the phase error is \( O(1) \) after \( 100 \) turnover times. Fig. B.3(b) supports our claim that replacing \( M^{-1} \) by \( (1 + A)M^{-1} \) corrects the dispersion error of the lumped mass matrix.

We show in Fig. B.4 the Galerkin solution of the one-dimensional transport problem with a step function as initial data. The solution shown in Fig. B.4 has been computed at \( T = 1 \) using the lumped mass matrix on a uniform mesh composed of 100 cells. The solution shown in Fig. B.3(b) and (c) have been obtained by replacing \( M^{-1} \) by \( (1 + A)M^{-1} \) and \( (1 + A + A^2 + A^3)M^{-1} \), respectively. Fig. B.4 also confirms that replacing \( M^{-1} \) by \( (1 + A)M^{-1} \) corrects the dispersion error of the lumped mass matrix even for non-smooth solutions.

Of course, the Galerkin method must be stabilized to get rid of the spurious oscillations. As shown in Section 5.6, stabilization has a marginal effect on dispersion.
