

12.4: Tangent Planes and Differentials

Suppose that $f(x, y)$ has continuous first partial derivatives and a surface S has equation $z = f(x, y)$. Let $P(x_0, y_0, z_0)$ be a point on S , i.e. $z_0 = f(x_0, y_0)$.

Denote by C_1 the trace to $f(x, y)$ for the plane $y = y_0$ and denote by C_2 the trace to $f(x, y)$ for the plane $x = x_0$. Let L_1 be the tangent line to the trace C_1 and let L_2 be the tangent line to the trace C_2 .

The **tangent plane** to the surface S (or to the graph of $f(x, y)$) at the point P is defined to be the plane that contains both the tangent lines L_1 and L_2 .

THEOREM 1. An equation of the tangent plane to the graph of the function $z = f(x, y)$ at the point $P(x_0, y_0, f(x_0, y_0))$ is

$$z - f(x_0, y_0) = f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0).$$

CONCLUSION: A normal vector to the tangent plane to the surface $z = f(x, y)$ at the point $P(x_0, y_0, f(x_0, y_0))$ is

$$\mathbf{n} = \mathbf{n}(x_0, y_0) = \langle \quad , \quad , \quad \rangle.$$

The line through the point $P(x_0, y_0, f(x_0, y_0))$ parallel to the vector \mathbf{n} is perpendicular to the above tangent plane. This line is called **the normal line** to the surface $z = f(x, y)$ at P . It follows that this normal line can be expressed parametrically as

EXAMPLE 2. Find an equation of the tangent plane to the graph of the function $z = x^2 + y^2 + 8$ at the point $(1, 1)$.

EXAMPLE 3. Find parametric equations for the normal line to the surface $z = e^{4y} \sin(4x)$ at the point $P(\pi/8, 0, 1)$

Differentials. Given $z = f(x, y)$. If Δx and Δy are given increments of $x = a$ and $y = b$ respectively, then the corresponding **increment** of z is

$$\Delta z(a, b) = f(a + \Delta x, b + \Delta y) - f(a, b). \tag{1}$$

¹the pictures are from our textbook

The **differentials** dx and dy are independent variables. The **differential** dz (or the **total differential**) is defined by

$$dz = \frac{\partial z}{\partial x}dx + \frac{\partial z}{\partial y}dy.$$

FACT: $\Delta z \approx dz$.

This implies:

$$f(a + \Delta x, b + \Delta y) \approx f(a, b) + dz(a, b)$$

or

EXAMPLE 4. Use differentials to find an approximate value for $\sqrt{1.03^2 + 1.98^3}$.

If $u = f(x, y, z)$ then the differential du at the point $(x, y, z) = (a, b, c)$ is defined in terms of the differentials dx , dy and dz of the independent variables:

$$du(a, b, c) = f_x(a, b, c)dx + f_y(a, b, c)dy + f_z(a, b, c)dz.$$

EXAMPLE 5. *The dimensions of a closed rectangular box are measured as 80 cm, 60 cm and 50 cm, respectively, with a possible error of 0.2 cm in each dimension. Use differentials to estimate the maximum error in calculating the surface area of the box.*

*A function $f(x, y)$ is **differentiable** at (a, b) if its partial derivatives f_x and f_y exist and are continuous at (a, b) .*

For example, all polynomial and rational functions are differentiable on their natural domains.

Let a surface S be a graph of a differentiable function f . As we zoom in toward a point on the surface S , the surface looks more and more like a plane (its tangent plane) and we can approximate the function f by a linear function of two variables.

$$f(x, y) \approx f(a, b) + f_x(a, b)(x - a) + f_y(a, b)(y - b) =: L(x, y).$$
