Cohomology of Hopf Algebras
Sarah Witherspoon

Group algebras are Hopf algebras, and their Hopf structure plays crucial roles in representation theory and cohomology of groups. A Hopf algebra is an algebra $A$ (say over a field $k$) that has a comultiplication $(\Delta : A \to A \otimes_k A)$ generalizing the diagonal map on group elements, an augmentation $(\varepsilon : A \to k)$ generalizing the augmentation on a group algebra, and an antipode $(S : A \to A)$ generalizing the inverse map on group elements. Hopf algebras of interest include group algebras, universal enveloping algebras of Lie algebras, restricted enveloping algebras, quantum groups, coordinate rings of groups, and more. The category of modules of a Hopf algebra $A$ is a tensor category with unit object and duals; this extra structure on the category arises from the comultiplication, augmentation, and antipode. Denote the unit object (that is, trivial module) by $k$. The cohomology of $A$ is

$$H^*(A) := \text{Ext}^*_A(k, k).$$

The cohomology of $A$ generally has some of the same properties as group cohomology: It is an algebra under a cup product arising from the tensor product of resolutions, equivalently Yoneda composition. It is graded commutative. If $M$ is an $A$-module, then $\text{Ext}^*_A(M, M)$ is an $H^*(A)$-module by tensoring with $M$. These are some of the ingredients required for a support variety theory of modules.

My research involves the structure of Hopf algebra cohomology, support variety theory, and applications for various types of finite dimensional Hopf algebras. The following conjecture motivates some of my work.

**Conjecture** (Etingof and Ostrik 2004 [3]) If $A$ is a finite dimensional Hopf algebra, then $H^*(A)$ is finitely generated.

In fact, Etingof and Ostrik conjectured more generally that the cohomology of a finite tensor category is finitely generated.

An obstacle to proving the conjecture, and thus simultaneously generalizing all these results, is that mathematicians do not yet understand the structure of Hopf
algebras well enough. Work on the conjecture thus far has involved investigations
for many different specific types of Hopf algebras. As a cautionary remark, an
analogous conjecture of Snashall and Solberg [14], involving Hochschild cohomol-
yogy of finite dimensional algebras, has a counterexample found by Xu [16].

In [11] with Mastnak, Pevtsova, and Schauenburg, we proved the conjecture for
finite dimensional pointed Hopf algebras with abelian groups of grouplike elements
(in characteristic 0) under some conditions on the parameters. Pointed Hopf
algebras are those whose duals are basic algebras, and they include the small
quantum groups. They have underlying algebra structure that of deformations of
skew group algebras. In [12] with Nguyễn, we proved the conjecture for some types
of Hopf algebras in positive characteristic whose underlying algebra structure is
that of a skew group algebra.

As special cases of some of these Hopf algebras (in characteristic 0), there is
a quantum analog of elementary abelian groups whose cohomology is easily seen
to be finitely generated. In [13] with Pevtsova, we developed support variety
theory for these quantum elementary abelian groups and proved a tensor product
theorem, that is,

$$V(M \otimes N) = V(M) \cap V(N)$$

for finite dimensional modules $M, N$ of a quantum elementary abelian group $A$,
where $V(-)$ denotes the variety. (These support varieties are defined in the usual
way, as maximal ideal spectra of quotients by annihilators of $\text{Ext}_A^*(M, M)$ in $H^*(A)$.) We classified ideals in the stable module category as an application of the
support variety theory.

With Feldvoss in [7], we developed a support variety theory more generally
for finite dimensional Hopf algebras. The theory was sufficiently strong to prove
some standard results on representation type in the case that the Hopf algebra
is quasitriangular (i.e. a tensor product of modules is commutative up to iso-
morphism), a condition that quantum groups satisfy. We used the containment $V(M \otimes N) \subset V(M) \cap V(N)$ that holds generally for quasitriangular Hopf algebras,
as well as a standard relationship between complexity and varieties of modules.

With Benson in [2], we showed that there are some Hopf algebras whose support
variety theory behaves quite differently from that of finite groups. In particular,
we constructed Hopf algebras $A$ from pairs of finite groups for which there are
modules $M, N$ such that

$$V(M \otimes N) \neq V(M) \cap V(N),$$

and in fact we have examples showing that neither containment holds in general.
We have examples of nonprojective modules for which a tensor power is projective.
These examples are special cases of a general construction of Hopf algebras

$$A := kH \otimes_k k[G]$$
where $G, H$ are finite groups with $G$ acting on $H$. That is, the underlying algebra structure of $A$ is just a tensor product of the group algebra $kH$ with the coordinate ring $k[G]$ of $G$. Comultiplication involves the group action, leading to noncommutativity of the tensor product of modules, and to the unusual behavior mentioned above. Nonetheless, there is a reasonably well-behaved support variety theory, based on that of finite groups, that we used to classify ideals in the stable module category.

This work is only a beginning; it shows plainly that there is much more to do in order to understand cohomology and varieties for modules of finite dimensional Hopf algebras generally. The potential rewards are great, as there are usually many applications of support varieties to representation-theoretic questions.
