Denote by $\Pi_{n}$ the set of all real algebraic polynomials of degree at most $n$. We define the class

$$
\Pi_{n}(s)=\left\{p \in \Pi_{n}: m(\{x \in[-1,1]:|p(x)| \leqslant 1\}) \geqslant 2-s\right\} \quad(0<s<2)
$$

where $m(A)$ denotes the Lebesgue measure of $A$. How large can the maximum modulus be on $[-1,1]$ for polynomials from $\Pi_{n}(s)$ ? In [7] E. J. Remez answered this question establishing the best possible upper bound. The solution and one of its applications in the theory of orthogonal polynomials can be found in [5] as well. Remez-type inequalities and their applications were studied in [1-3]. The purpose of this paper is to prove a sharp Remez-type inequality for constrained polynomials.

Remez's inequality asserts that

$$
\begin{equation*}
\max _{-1 \leqslant x \leqslant 1}|p(x)| \leqslant Q_{n}(4 /(2-s)-1) \quad\left(p \in \Pi_{n}(s), 0<s<2\right), \tag{1}
\end{equation*}
$$

where $Q_{n}(x)=\cos (n \arccos x)$ is the Chebyshev polynomial of degree $n$. For $a<b$ we define

$$
\begin{aligned}
& P_{n}(a, b) \\
& \quad=\left\{p: p(x)=\sum_{j=0}^{n} \alpha_{j}(b-x)^{j}(x-a)^{n-j} \text { with all } \alpha_{j} \geqslant 0 \text { or all } \alpha_{j} \leqslant 0\right\}
\end{aligned}
$$

The class $P_{n}(-1,1)$ was introduced and examined thoroughly by $G$. $G$. Lorentz in [6], subsequently a number of properties were ohtained in [4]. By an observation of Lorentz, if $p \in \Pi_{n}$ has no zero in the open unit circle then $p \in P_{n}(-1,1)$. In this paper we prove the following sharp Remez-type theorem for polynomials from $P_{n}(-1,1)$.

Theorem. We have

$$
\begin{equation*}
\max _{-1 \leqslant x \leqslant 1}|p(x)| \leqslant(1-s / 2)^{-n} \quad\left(p \in P_{n}(-1,1) \cap \Pi_{n}(s), 0<s<2\right) \tag{2}
\end{equation*}
$$

and the equality holds only for the polynomials $\pm(1 \pm x)^{n} /(2-s)^{n}$.
Corollary. If $p \in \Pi_{n}(s)$ has no zero in the open unit circle then (2) holds.

Proof of the Theorem. Observe that $[c, d] \subset[a, b]$ implies $P_{n}(a, b) \subset$ $P_{n}(c, d)$. This follows simply from the definition and the substitutions

$$
\begin{aligned}
& b-x=\frac{b-c}{d-c}(d-x)+\frac{b-d}{d-c}(x-c) \\
& x-a=\frac{c-a}{d-c}(d-x)+\frac{d-a}{d-c}(x-c)
\end{aligned}
$$

where $(b-c) /(d-c),(b-d) /(d-c),(c-a) /(d-c)$, and $(d-a) /(d-c)$ are non-negative. Let $p \in P_{n}(a, b)$ with the representation

$$
\begin{equation*}
p(x)=\sum_{j=0}^{n} \alpha_{j}(b-x)^{j}(x-a)^{n-j} \quad \text { with all } \alpha_{j} \geqslant 0 \text { or all } \alpha_{j} \leqslant 0 \tag{3}
\end{equation*}
$$

Then for $0<s<2$ we easily deduce

$$
\begin{align*}
|\dot{p}(b)| & =\left|\alpha_{0}\right|(b-a)^{n}=\left(\frac{b-a}{y-a}\right)^{n}\left|\alpha_{0}\right|(y-a)^{n} \leqslant\left(\frac{b-a}{y-a}\right)^{n}|p(y)| \\
& \leqslant(1-s / 2)^{-n}|p(y)| \quad(b-(b-a) s / 2 \leqslant y \leqslant b) \tag{4}
\end{align*}
$$

and similarly

$$
\begin{equation*}
|p(a)| \leqslant(1-s / 2)^{-n}|p(y)| \quad(a \leqslant y \leqslant a+(b-a) s / 2) \tag{5}
\end{equation*}
$$

Now let $p \in P_{n}(-1,1) \cap \Pi_{n}(s)(0<s<2)$, and choose a $z \in[-1,1]$ such that

$$
\begin{equation*}
|p(z)|=\max _{-1 \leqslant x \leqslant 1}|p(x)| \tag{6}
\end{equation*}
$$

Since $p \in \Pi_{n}(s)$, there is a $y$ from either $[z-s(z+1) / 2, z]$ or $[z, z+s(1-z) / 2]$ such that $|p(y)| \leqslant 1$. In the first case the relation $P_{n}(-1,1) \subset P_{n}(-1, z)$ and (4) yield the desired result, and in the second case the relation $P_{n}(-1,1) \subset P_{n}(z, 1)$ and (5) give the theorem.
