Linear Algebra

**Lecture 25:
Eigenvalues and eigenvectors
of a linear operator.**

Eigenvalues and eigenvectors of a matrix

Definition. Let A be an $n \times n$ matrix. A number $\lambda \in \mathbb{R}$ is called an **eigenvalue** of the matrix A if $\boxed{A\mathbf{v} = \lambda\mathbf{v}}$ for a nonzero column vector $\mathbf{v} \in \mathbb{R}^n$. The vector $\mathbf{v}$ is called an **eigenvector** of A belonging to (or associated with) the eigenvalue λ.

If λ is an eigenvalue of A then the nullspace $N(A - \lambda I)$, which is nontrivial, is called the **eigenspace** of A corresponding to λ. The eigenspace consists of all eigenvectors belonging to the eigenvalue λ plus the zero vector.

Characteristic equation

Definition. Given a square matrix A, the equation $\det(A - \lambda I) = 0$ is called the **characteristic equation** of A.

Eigenvalues λ of A are roots of the characteristic equation.

If A is an $n \times n$ matrix then $p(\lambda) = \det(A - \lambda I)$ is a polynomial of degree n. It is called the **characteristic polynomial** of A.

Theorem Any $n \times n$ matrix has at most n eigenvalues.

Example. $A = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$.

Characteristic equation: $\begin{vmatrix} 2-\lambda & 1 \\ 1 & 2-\lambda \end{vmatrix} = 0$.

$(2-\lambda)^2 - 1 = 0 \implies \lambda_1 = 1, \;\; \lambda_2 = 3$.

$$(A - I)\mathbf{x} = \mathbf{0} \iff \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

$$\iff \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \iff x + y = 0.$$

The general solution is $(-t, t) = t(-1, 1), \;\; t \in \mathbb{R}$.
Thus $\mathbf{v}_1 = (-1, 1)$ is an eigenvector associated
with the eigenvalue 1. The corresponding
eigenspace is the line spanned by $\mathbf{v}_1$.

$$(A - 3I)\mathbf{x} = \mathbf{0} \iff \begin{pmatrix} -1 & 1 \\ 1 & -1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

$$\iff \begin{pmatrix} 1 & -1 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \iff x - y = 0.$$

The general solution is $(t, t) = t(1, 1), \ t \in \mathbb{R}$.

Thus $\mathbf{v}_2 = (1, 1)$ is an eigenvector associated with the eigenvalue 3. The corresponding eigenspace is the line spanned by $\mathbf{v}_2$.

Summary. $A = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$.

- The matrix A has two eigenvalues: 1 and 3.

- The eigenspace of A associated with the eigenvalue 1 is the line $t(-1, 1)$.

- The eigenspace of A associated with the eigenvalue 3 is the line $t(1, 1)$.

- Eigenvectors $\mathbf{v}_1 = (-1, 1)$ and $\mathbf{v}_2 = (1, 1)$ of the matrix A form a basis for $\mathbb{R}^2$.

- Geometrically, the mapping $\mathbf{x} \mapsto A\mathbf{x}$ is a stretch by a factor of 3 away from the line $x + y = 0$ in the orthogonal direction.

Example. $A = \begin{pmatrix} 1 & 1 & -1 \\ 1 & 1 & 1 \\ 0 & 0 & 2 \end{pmatrix}$.

Characteristic equation:

$$\begin{vmatrix} 1-\lambda & 1 & -1 \\ 1 & 1-\lambda & 1 \\ 0 & 0 & 2-\lambda \end{vmatrix} = 0.$$

Expand the determinant by the 3rd row:

$$(2-\lambda) \begin{vmatrix} 1-\lambda & 1 \\ 1 & 1-\lambda \end{vmatrix} = 0.$$

$$\big((1-\lambda)^2 - 1\big)(2-\lambda) = 0 \iff -\lambda(2-\lambda)^2 = 0$$
$$\implies \lambda_1 = 0, \ \lambda_2 = 2.$$

$$A\mathbf{x} = \mathbf{0} \iff \begin{pmatrix} 1 & 1 & -1 \\ 1 & 1 & 1 \\ 0 & 0 & 2 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

Convert the matrix to reduced row echelon form:

$$\begin{pmatrix} 1 & 1 & -1 \\ 1 & 1 & 1 \\ 0 & 0 & 2 \end{pmatrix} \rightarrow \begin{pmatrix} 1 & 1 & -1 \\ 0 & 0 & 2 \\ 0 & 0 & 2 \end{pmatrix} \rightarrow \begin{pmatrix} 1 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$$

$$A\mathbf{x} = \mathbf{0} \iff \begin{cases} x + y = 0, \\ z = 0. \end{cases}$$

The general solution is $(-t, t, 0) = t(-1, 1, 0)$, $t \in \mathbb{R}$. Thus $\mathbf{v}_1 = (-1, 1, 0)$ is an eigenvector associated with the eigenvalue 0. The corresponding eigenspace is the line spanned by $\mathbf{v}_1$.

$$(A - 2I)\mathbf{x} = \mathbf{0} \iff \begin{pmatrix} -1 & 1 & -1 \\ 1 & -1 & 1 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

$$\iff \begin{pmatrix} 1 & -1 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix} \iff x - y + z = 0.$$

The general solution is $x = t - s$, $y = t$, $z = s$, where $t, s \in \mathbb{R}$. Equivalently,

$$\mathbf{x} = (t - s, t, s) = t(1, 1, 0) + s(-1, 0, 1).$$

Thus $\mathbf{v}_2 = (1, 1, 0)$ and $\mathbf{v}_3 = (-1, 0, 1)$ are eigenvectors associated with the eigenvalue 2. The corresponding eigenspace is the plane spanned by $\mathbf{v}_2$ and $\mathbf{v}_3$.

Summary. $A = \begin{pmatrix} 1 & 1 & -1 \\ 1 & 1 & 1 \\ 0 & 0 & 2 \end{pmatrix}$.

- The matrix A has two eigenvalues: 0 and 2.

- The eigenvalue 0 is *simple:* the corresponding eigenspace is a line.

- The eigenvalue 2 is of *multiplicity* 2: the corresponding eigenspace is a plane.

- Eigenvectors $\mathbf{v}_1 = (-1, 1, 0)$, $\mathbf{v}_2 = (1, 1, 0)$, and $\mathbf{v}_3 = (-1, 0, 1)$ of the matrix A form a basis for $\mathbb{R}^3$.

- Geometrically, the map $\mathbf{x} \mapsto A\mathbf{x}$ is the projection on the plane $\mathrm{Span}(\mathbf{v}_2, \mathbf{v}_3)$ along the lines parallel to $\mathbf{v}_1$ with the subsequent scaling by a factor of 2.

Eigenvalues and eigenvectors of an operator

Definition. Let V be a vector space and $L : V \to V$ be a linear operator. A number λ is called an **eigenvalue** of the operator L if $\boxed{L(\mathbf{v}) = \lambda \mathbf{v}}$ for a nonzero vector $\mathbf{v} \in V$. The vector $\mathbf{v}$ is called an **eigenvector** of L associated with the eigenvalue λ.

(If V is a functional space then eigenvectors are also called **eigenfunctions**.)

If $V = \mathbb{R}^n$ then the linear operator L is given by $L(\mathbf{x}) = A\mathbf{x}$, where A is an $n \times n$ matrix.
In this case, eigenvalues and eigenvectors of the operator L are precisely eigenvalues and eigenvectors of the matrix A.

Suppose $L : V \to V$ is a linear operator on a **finite-dimensional** vector space V.

Let $\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_n$ be a basis for V and $g : V \to \mathbb{R}^n$ be the corresponding coordinate mapping. Let A be the matrix of L with respect to this basis. Then

$$L(\mathbf{v}) = \lambda \mathbf{v} \iff A\, g(\mathbf{v}) = \lambda\, g(\mathbf{v}).$$

Hence the eigenvalues of L coincide with those of the matrix A. Moreover, the associated eigenvectors of A are coordinates of the eigenvectors of L.

Definition. The characteristic polynomial $p(\lambda) = \det(A - \lambda I)$ of the matrix A is called the **characteristic polynomial** of the operator L.

Then eigenvalues of L are roots of its characteristic polynomial.

Theorem. The characteristic polynomial of the operator L is well defined. That is, it does not depend on the choice of a basis.

Proof: Let B be the matrix of L with respect to a different basis $\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n$. Then $A = UBU^{-1}$, where U is the transition matrix from the basis $\mathbf{v}_1, \ldots, \mathbf{v}_n$ to $\mathbf{u}_1, \ldots, \mathbf{u}_n$. We have to show that $\det(A - \lambda I) = \det(B - \lambda I)$ for all $\lambda \in \mathbb{R}$. We obtain

$$\det(A - \lambda I) = \det(UBU^{-1} - \lambda I)$$
$$= \det\left(UBU^{-1} - U(\lambda I)U^{-1}\right) = \det\left(U(B - \lambda I)U^{-1}\right)$$
$$= \det(U)\det(B - \lambda I)\det(U^{-1}) = \det(B - \lambda I).$$

Eigenspaces

Let $L : V \to V$ be a linear operator.

For any $\lambda \in \mathbb{R}$, let V_λ denotes the set of all solutions of the equation $L(\mathbf{x}) = \lambda \mathbf{x}$.

Then V_λ is a *subspace* of V since V_λ is the *kernel* of a linear operator given by $\mathbf{x} \mapsto L(\mathbf{x}) - \lambda \mathbf{x}$.

V_λ minus the zero vector is the set of all eigenvectors of L associated with the eigenvalue λ. In particular, $\lambda \in \mathbb{R}$ is an eigenvalue of L if and only if $V_\lambda \neq \{\mathbf{0}\}$.

If $V_\lambda \neq \{\mathbf{0}\}$ then it is called the **eigenspace** of L corresponding to the eigenvalue λ.
