## MATH 433 <br> Applied Algebra

Lecture 4:
More on greatest common divisor. Prime numbers.
Unique factorisation theorem.

## Greatest common divisor

Given positive integers $a_{1}, a_{2}, \ldots, a_{n}$, the greatest common divisor $\operatorname{gcd}\left(a_{1}, a_{2}, \ldots, a_{n}\right)$ is the largest positive integer that divides $a_{1}, a_{2}, \ldots, a_{n}$.

Theorem (i) $\operatorname{gcd}\left(a_{1}, a_{2}, \ldots, a_{n}\right)$ is the smallest positive integer represented as an integral linear combination of $a_{1}, a_{2}, \ldots, a_{n}$.
(ii) $\operatorname{gcd}\left(a_{1}, a_{2}, \ldots, a_{n}\right)$ is divisible by any other common divisor of $a_{1}, a_{2}, \ldots, a_{n}$.
Remark. The theorem can be proved in the same way as in the case $n=2$ (see Lecture 2). Another approach is by induction on $n$ using the fact that $\operatorname{gcd}\left(a_{1}, a_{2}, \ldots, a_{n}\right)=\operatorname{gcd}\left(a_{1}, \operatorname{gcd}\left(a_{2}, \ldots, a_{n}\right)\right)$.

## Prime numbers

A positive integer $p$ is prime if it has exactly two positive divisors, namely, 1 and $p$.
Examples. 2, 3, 5, 7, 29, 41, 101.
A positive integer $n$ is composite if it a product of two strictly smaller positive integers.
Examples. $6=2 \cdot 3,16=4 \cdot 4,125=5 \cdot 25$.
Any positive integer is either prime or composite or 1. Prime factorisation of a positive integer $n \geq 2$ is a decomposition of $n$ into a product of primes.
Examples. - $120=12 \cdot 10=(2 \cdot 6) \cdot(2 \cdot 5)$
$=(2 \cdot(2 \cdot 3)) \cdot(2 \cdot 5)=2^{3} \cdot 3 \cdot 5$.

- $144=12^{2}=\left(2^{2} \cdot 3\right)^{2}=2^{4} \cdot 3^{2}$.

## Sieve of Eratosthenes

The sieve of Eratosthenes is a method to find all primes from 2 to $n$ :
(1) Write down all integers from 2 to $n$.
(2) Select the smallest integer $k$ that is not selected or crossed out yet.
(3) Cross out all multiples of $k$.
(4) If not all numbers are selected or crossed out, return to step (2).

The prime numbers are those selected in the process.

## Unique factorisation theorem

Theorem Any positive integer $n \geq 2$ admits a prime factorisation. This factorisation is unique up to rearranging the factors.

Corollary There are infinitely many prime numbers. Idea of the proof: Let $p_{1}, p_{2}, \ldots, p_{n}$ be the first $n$ primes. Consider the number $N=p_{1} p_{2} \cdots p_{n}+1$. This number must have a prime divisor different from $p_{1}, p_{2}, \ldots, p_{n}$.

Problem. Suppose $m$ is a positive integer such that

$$
\begin{aligned}
& m=2^{4} p_{1} p_{2} p_{3}, \\
& m+100=5 q_{1} q_{2} q_{3}, \\
& m+200=23 r_{1} r_{2} r_{3} r_{4},
\end{aligned}
$$

where $p_{i}, q_{j}, r_{k}$ are prime numbers and, moreover, $p_{i} \neq 2$, $q_{j} \neq 5, r_{k} \neq 23$. Find $m$.

The prime decomposition of 100 is $2^{2} \cdot 5^{2}$. Since the numbers $m+100$ and 100 are divisible by 5 , so are their difference $m$ and their sum $m+200$.
The prime decomposition of 200 is $2^{3} \cdot 5^{2}$. Since the number $m$ is divisible by $2^{4}=16$, it follows that $m+100$ is divisible by $2^{2}=4$ while $m+200$ is divisible by $2^{3}=8$.
By the above the prime decomposition of $m+200$ contains $2^{3} \cdot 5 \cdot 23$. As there are only 5 factors in this decomposition, the number $m+200$ is exactly $2^{3} \cdot 5 \cdot 23=920$. Then $m+100=820=2^{2} \cdot 5 \cdot 41$ and $m=720=2^{4} \cdot 3^{2} \cdot 5$.

## Unique prime factorisation

Theorem Any positive integer $n \geq 2$ admits a prime factorisation. This factorisation is unique up to rearranging the factors.

Ideas of the proof: The existence is proved by strong induction on $n$. It is based on a simple fact: if $p_{1} p_{2} \ldots p_{s}$ is a prime factorisation of $k$ and $q_{1} q_{2} \ldots q_{t}$ is a prime factorisation of $m$, then $p_{1} p_{2} \ldots p_{s} q_{1} q_{2} \ldots q_{t}$ is a prime factorisation of $k m$.

The uniqueness is proved by (normal) induction on the number of prime factors. It is based on a (not so simple) fact: if a prime number $p$ divides a product of primes $q_{1} q_{2} \ldots q_{t}$ then one of the primes $q_{1}, \ldots, q_{t}$ coincides with $p$.

## Coprime numbers

Positive integers $a$ and $b$ are relatively prime (or coprime) if $\operatorname{gcd}(a, b)=1$.

Theorem Suppose that $a$ and $b$ are coprime integers. Then
(i) $a \mid b c$ implies $a \mid c$;
(ii) $a \mid c$ and $b \mid c$ imply $a b \mid c$.

Idea of the proof: Since $\operatorname{gcd}(a, b)=1$, there are integers $m$ and $n$ such that $m a+n b=1$. Then $c=m a c+n b c$.

Corollary 1 If a prime number $p$ divides the product $a_{1} a_{2} \ldots a_{n}$, then $p$ divides one of the integers $a_{1}, \ldots, a_{n}$.

Corollary 2 If an integer $a$ is divisible by pairwise coprime integers $b_{1}, b_{2}, \ldots, b_{n}$, then $a$ is divisible by the product $b_{1} b_{2} \ldots b_{n}$.

Let $a=p_{1}^{n_{1}} p_{2}^{n_{2}} \ldots p_{k}^{n_{k}}$ and $b=p_{1}^{m_{1}} p_{2}^{m_{2}} \ldots p_{k}^{m_{k}}$, where $p_{1}, p_{2}, \ldots, p_{k}$ are distinct primes and $n_{i}, m_{i}$ are nonnegative integers.

Theorem (i) $a b=p_{1}^{n_{1}+m_{1}} p_{2}^{n_{2}+m_{2}} \ldots p_{k}^{n_{k}+m_{k}}$.
(ii) $a$ divides $b$ if and only if $n_{i} \leq m_{i}$ for $i=1,2, \ldots, k$.
(iii) $\operatorname{gcd}(a, b)=p_{1}^{s_{1}} p_{2}^{s_{2}} \ldots p_{k}^{s_{k}}$, where $s_{i}=\min \left(n_{i}, m_{i}\right)$.
(iv) $\operatorname{lcm}(a, b)=p_{1}^{t_{1}} p_{2}^{t_{2}} \ldots p_{k}^{t_{k}}$, where $t_{i}=\max \left(n_{i}, m_{i}\right)$.

Here $\operatorname{lcm}(a, b)$ denotes the least common multiple of $a$ and $b$, that is, the smallest positive integer divisible by both $a$ and $b$.
