

Last time: Properties of the FT + Sampling Thm.

Today = Proof of Resampling Thm. Proof of Samp. Thm + Asymptotic analysis.

1. Sampling Theorem  $f \in L^2(\mathbb{R})$ ,  $\text{supp}(f) \subseteq [-R, R]$ ,

$$f(x) = \sum_{k=-\infty}^{\infty} f\left(\frac{k\pi}{2}\right) \frac{\sin((2x - k\pi))}{2x - k\pi}.$$

Proof: Expand  $\hat{f}(\xi)$  in a Fourier series over the interval  $[-R, R]$ :

$$(*) \quad \hat{f}(\xi) = \sum_{n=-\infty}^{\infty} d_n e^{\frac{i n \pi \xi}{2}}, \quad d_n = \frac{1}{2\pi} \int_{-\pi}^{\pi} \hat{f}(\xi) e^{-i \frac{n \pi \xi}{2}} d\xi.$$

$$\text{Note: } f(x) = \frac{1}{2\pi} \int_{-\pi}^{\pi} \hat{f}(\xi) e^{\frac{i \xi x}{2}} d\xi, \text{ so so}$$

Inversion thm,

$$d_n = \frac{\pi}{2} \left( \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) e^{-i \frac{(n\pi)}{2} x} dx \right) = \frac{\pi}{2} f(-\frac{n\pi}{2}).$$

In (\*), change  $n \rightarrow -k$ . Then,

$$\hat{f}(\xi) = \sum_{k=-\infty}^{\infty} d_{-k} e^{-i \frac{k\pi}{2} \xi} = \sum_{k=-\infty}^{\infty} \frac{\pi}{2} f\left(\frac{k\pi}{2}\right) e^{-i \frac{k\pi}{2} \xi},$$

$$f(x) = \frac{1}{2\pi} \int_{-\pi}^{\pi} \hat{f}(\xi) e^{i \xi x} d\xi = \sum_{k=-\infty}^{\infty} \frac{\pi}{2} f\left(\frac{k\pi}{2}\right) \int_{-\pi}^{\pi} e^{i \xi x} e^{-i \xi \frac{k\pi}{2}} d\xi = \frac{\sin((2x - k\pi))}{2x - k\pi}.$$

~~$$\text{Therefore } f(x) = \sum_{k=-\infty}^{\infty} f\left(\frac{k\pi}{2}\right) \frac{\sin((2x - k\pi))}{2x - k\pi}.$$~~

\* Scale the usual formula for the Fourier series,  
i.e., if we are  $f(x + T) = f(x)$  for  $x \rightarrow \frac{i\pi k}{2}$ , etc.

## 2 Asymptotic Analysis

Basic terms We are going to discuss mainly, large  $x^n$  behavior behavior of functions.

Big "oh" notation  $f(x) = O(x^{-\alpha})$  as  $x \rightarrow \infty$  means there is a constant  $C$  independent of  $x$ ;  $\alpha$  such that  $|f(x)| \leq Cx^{-\alpha}$ , for  $x$  large.

Little "oh"  $f(x) = o(x^{-\alpha})$  means that

$$\lim_{x \rightarrow \infty} \frac{f(x)}{x^\alpha} = 0$$

Examples.  $\frac{1}{x^2 + 1} = O(x^{-2})$  and  $\frac{1}{x^2 + 1} - x^{-2} = o(x^{-2})$ .

Asymptotics. (a)  $P(x+1) = \sqrt{\pi} x^{k+\frac{1}{2}} e^{-x} (1 + O(x^{-1}))$ .

This means that  $\frac{P(x+1)}{x^{k+\frac{1}{2}} e^{-x}} = 1 + O(x^{-1})$ .

Note:  $\lim_{x \rightarrow \infty} P(x+1) = +\infty$ .

Note:

$$P(x+1) - x^{k+\frac{1}{2}} e^{-x} = O(x^{k-\frac{1}{2}} e^{-x}) \rightarrow 0.$$

We are not saying that the difference goes to 0, only the ratio  $\rightarrow 0$ .

Relative error or abs. error (2) Avgard no's number  
 $6.02 \times 10^{23}$  If we drop  $n_0$ , it's still a good relative

(3)

Relative error or absolute error Avogadro's number  $\approx 6.02 \times 10^{23}$

If we drop  $6.02 \times 10^{23}$ , it's still a reasonable approximation — in a relative sense!

$$\frac{6.02 \times 10^{23}}{6 \times 10^{23}} \approx 1 + 10^{-3} \times \frac{1}{3} \approx 1 + 3 \times 10^{-4},$$

The absolute error is  $6.02 \times 10^{23} - 6.00 \times 10^{23} = 2 \times 10^{21}$   
which is huge!!

Asymptotic approximations are generally relative.

Asymptotic sense

It turns out that, in

$$V(1+x) = \sqrt{2\pi} x^{x+\frac{1}{2}} e^{-x} \left( 1 + \frac{1}{12x} + \frac{1}{288x^2} + \dots \right),$$

where equality is taken in an asymptotic sense. The series  $1 + \frac{1}{12x} + \frac{1}{288x^2} + \dots$  is divergent. What we mean is that we will get ~~at a good~~ a better approximation if we add terms — but, this will only be better for  $x$  ~~suffi~~ taken to be very large.

$$t = x(u-1)$$

$$\text{Another Example } Ei(x) = \int_x^\infty \frac{e^{-t}}{t} dt = e^{-x} \int_0^\infty \frac{e^{-tu}}{1+u} du.$$

has the asymptotic expansion

$$Ei(x) \approx e^{-x} \left( \sum_{k=0}^{\infty} (-1)^k \frac{x^k}{k!} \right), \text{ which is clearly divergent.}$$

3. Watson's Lemma Frequently, we want to find asymptotic expansions for quantities like

$$\int_0^\infty f(t) e^{-xt} dt, \quad \int_{-\alpha}^0 f(t) e^{-xt} dt, \text{ etc.}$$

Watson's Lemma Suppose that  $f(t) \in L_p([t_0, \infty))$  and that for  $0 \leq t \leq T$ ,  $f(t) = \sum_{k=1}^{\infty} a_k t^{\frac{k}{n}-1}$ , then

$$(1) F(x) := \int_0^\infty f(t) e^{-xt} dt \sim \sum_{k=1}^{\infty} a_k x^{-\frac{k}{n}} \Gamma\left(\frac{k}{n}\right).$$

Remark. (1)  $f(t)$  doesn't need to have a complete series expansion, only one with a finite number of terms will do.

(2) Be expansion that one gets, namely (1), is of exactly what one would get if one interchanges (improperly!) the sum and integral:

$$\sum_{k=1}^{\infty} \int_0^\infty f(t) e^{-xt} dt = \sum_{k=1}^{\infty} a_k \int_0^\infty t^{\frac{k}{n}-1} e^{-xt} dt$$

$\text{if } u = xt, \text{ integral} \\ = x^{-\frac{k}{n}} \Gamma\left(\frac{k}{n}\right)$

So even though it's wrong the end result is correct,

Proof: (1)  $F(x) = \int_0^T f(t) e^{-xt} dt + \int_T^\infty f(t) e^{-xt} dt.$

$$(2) \left| \int_T^\infty f(t) e^{-xt} dt \right| \leq \|f\|_{L^p([T, \infty))} \|e^{-xt}\|_{L^q([T, \infty))}$$

$$\text{use } \|e^{-xt}\|_{L^q([T, \infty))} = \left( \int_T^\infty e^{-qx} dx \right)^{1/q} = \left( \frac{e^{-qT}}{qx} \right)^{1/q} = q^{-1/2} x^{-1/2} e^{-xT},$$

$$\Rightarrow \left| \int_T^\infty f(x) e^{-xt} dt \right| \leq \|f\|_{L^1(\omega)} \cdot \|e^{-xt}\|_{L^2(T, \omega)}$$

$$\Rightarrow \left| \int_T^\infty f(x) e^{-xt} dt \right| \leq \|f\|_{L^1(T, \omega)} \cdot e^{-t - \frac{t}{2}} e^{-xT}$$

$$\Rightarrow \left| \int_T^\infty f(x) e^{-xt} dt \right| = O(x^{-1/2} e^{-xT}).$$

(2) We will need another inequality:

$$\int_T^\infty t^{\alpha-1} e^{-xt} dt \leq C x^{-\frac{x}{2}} e^{-\frac{xT}{2}} P(\alpha)$$

$$C P(\alpha) x^{-1} e^{-\frac{xT}{2}}.$$

$$\begin{aligned} \text{Proof: } \int_T^\infty t^{\alpha-1} e^{-xt} dt &= \int_T^\infty t^{\alpha-1} e^{-\frac{xt}{2}} e^{-\frac{xt}{2}} dt \\ &\leq \left( \int_T^\infty t^{\alpha-1} e^{-\frac{xt}{2}} dt \right) \left( e^{-\frac{xt}{2}} \right) \left( e^{-\frac{xt}{2}} \right)^{\alpha-1} \\ &\leq \underbrace{\left( \int_0^\infty t^{\alpha-1} e^{-\frac{xt}{2}} dt \right)}_{= (2/\pi)^{\alpha/2} P(\alpha)} \cdot e^{-\frac{xT}{2}} \\ &= (2/\pi)^{\alpha/2} P(\alpha) e^{-xT/2}. \\ &\quad \text{Since } 2^{\alpha/2} x^{-\alpha/2} P^2(\alpha) = e^{-xT/2}, \end{aligned}$$

Finish this up next time.
