Section 1.1: Vectors

Quantities that we measure that have magnitude but not direction are called **scalars**.

DEFINITION 1. *A **vector** is a quantity that has both magnitude and direction. A 2-dimensional vector is an ordered pair* $\mathbf{a} = \langle a_1, a_2 \rangle$. *The numbers* a_1 *and* a_2 *are called the **components** of the vector* $\mathbf{a}$.

Typical notation to designate a vector is a boldfaced character or a character with and arrow on it (i.e. $\mathbf{a}$ or $\vec{a}$).

DEFINITION 2. *Given the points* $A(a_1, a_2)$ *and* $B(b_1, b_2)$, *the vector* $\mathbf{a}$ *with representation* $\overrightarrow{AB}$ *is*

$$\overrightarrow{AB} = \langle b_1 - a_1, b_2 - a_2 \rangle .$$

The point A *here is initial point and* B *is terminal one.*

A vector with the initial point located at the origin is called the **position** vector (or we say that a vector is in standard position).

Vectors are equal if they have the same length and direction (same slope).

EXAMPLE 3. *Graph the vector with initial point A(1, -2) and terminal point B(2,1). Find the components of* $\overrightarrow{AB}$ *and* $\overrightarrow{BA}$.

Vector operations

- *Scalar Multiplication*: If c is a scalar and $\mathbf{a} = \langle a_1, a_2 \rangle$, then

$$c\mathbf{a} = c \langle a_1, a_2 \rangle = \langle ca_1, ca_2 \rangle .$$

DEFINITION 4. *Two vectors* $\mathbf{a}$ *and* $\mathbf{b}$ *are called* **parallel** *if* $\mathbf{b} = c\mathbf{a}$ *with some scalar* c.

If $c > 0$ then a and ca have the same direction, if $c < 0$ then a and ca have the opposite direction.

- *Vector addition*: If $\mathbf{a} = \langle a_1, a_2 \rangle$ and $\mathbf{b} = \langle b_1, b_2 \rangle$ then

$$\mathbf{a} + \mathbf{b} = \langle a_1 + b_1, a_2 + b_2 \rangle .$$

Triangle Law **Parallelogram Law**

$\mathbf{a} + \mathbf{b}$ is called the **resultant vector**

EXAMPLE 5. *Let* $\mathbf{a} = \langle -1, 2 \rangle$ *and* $\mathbf{b} = \langle 2.1, -0.5 \rangle$. *Then* $3\mathbf{a} + 2\mathbf{b} =$

The **magnitude** or **length** of a vector $\mathbf{a} = \langle a_1, a_2 \rangle$ is denoted by $|\mathbf{a}|$,

$$|\mathbf{a}| =$$

EXAMPLE 6. *Find:* $|\langle 3, -8 \rangle|$, $\left| \left\langle \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2} \right\rangle \right|$, $|\mathbf{0}|$

A **unit** vector is a vector with length one. Any vector can be made into a unit vector by dividing it by its length. So, a unit vector in the direction of $\mathbf{a}$ is

$$\mathbf{u} = \frac{\mathbf{a}}{|\mathbf{a}|}.$$

Any vector $\mathbf{a}$ can be fully represented by providing its length, $|\mathbf{a}|$ and a unit vector $\mathbf{u}$ in its direction:

$$\mathbf{a} = |\mathbf{a}|\, \mathbf{u}$$

EXAMPLE 7. *Given* $\mathbf{a} = \langle 2, -1 \rangle$. *Find*

(a) *a unit vector that has the same direction as* $\mathbf{a}$*;*

(b) *a vector* $\mathbf{b}$ *in the direction opposite to* $\mathbf{a}$ *s.t* $|\mathbf{b}| = 7$.

The **standard basis vectors** are given by the unit vectors $\mathbf{i} = \langle 1, 0 \rangle$ and $\mathbf{j} = \langle 0, 1 \rangle$ along the x and y directions, respectively. Using the basis vectors, one can represent any vector $\mathbf{a} = \langle a_1, a_2 \rangle$ as

$$\mathbf{a} = a_1\mathbf{i} + a_2\mathbf{j}.$$

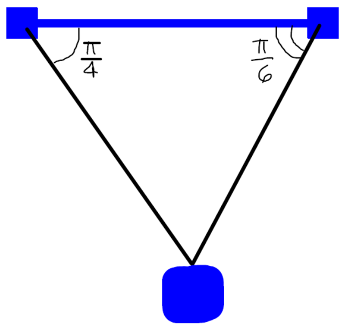
EXAMPLE 8. *Given* $\mathbf{a} = 2\mathbf{i} - \mathbf{j}$, $\mathbf{b} = \langle 5, -2 \rangle$. *Find a scalars* s *and* t *such that* $s\mathbf{a} + t\mathbf{b} = -4\mathbf{j}$.

Applications: Quantities such as force, displacement or velocity that have direction as well as magnitude are represented by vectors.

EXAMPLE 9. *Ben walks due west on the deck of a ship at 5 mph. The ship is moving north at a speed of 25 mph. Find the direction and speed of Ben relative to the surface of the water.*

EXAMPLE 10. *Two forces F_1 and F_2 with magnitudes 14 pounds and 12 pounds act on an object at a point P as shown. Find the resultant force as well as it's magnitude and direction.*

EXAMPLE 11. *An 60 pound weight hangs from two wires as shown. Find the tensions (forces) in both wires and their magnitudes.*



EXAMPLE 12. *An airplane, flying due east at an airspeed of 450mph, encounters a 50-mph wind acting in the direction of* $E60^o N$ *(60^o North of East). The airplane holds its compass heading due east but, because of the wind, acquires a new ground speed (i.e. the magnitude of the resultant) and direction. What are they?*
