## 25: Systems of Linear Algebraic Equations. Eigenvalues and Eigenvectors (section 7.3)

## Eigenvalues and Eigenvectors

1. A number $\lambda$ is called an eigenvalue of matrix $A$ if there exists a nonzero vector $v$ such that

$$
A v=\lambda v
$$

and $v$ is called an eigenvector corresponding to the eigenvalue $\lambda$.
2. Example. If $A$ is diagonal matrix,

$$
A=\left(\begin{array}{cccc}
\lambda_{1} & 0 & \ldots & 0 \\
0 & \lambda_{2} & \ldots & 0 \\
\vdots & \vdots & \ldots & \vdots \\
0 & 0 & \ldots & \lambda_{n}
\end{array}\right)
$$

then the numbers $\lambda_{1}, \lambda_{2}, \ldots, \lambda_{n}$ are eigenvalues and the vectors

$$
v_{1}=\left(\begin{array}{c}
1 \\
0 \\
\vdots \\
0
\end{array}\right), \quad v_{2}=\left(\begin{array}{c}
0 \\
1 \\
\vdots \\
0
\end{array}\right), \ldots, \quad v_{n}=\left(\begin{array}{c}
0 \\
0 \\
\vdots \\
1
\end{array}\right)
$$

are the corresponding eigenvectors.
3. How to find eigenvalues?

Eigenvalue are solutions of the following characteristic equation (polynomial):

$$
\operatorname{det}(A-\lambda I)=0
$$

4. Show that the characteristic equation in the case $n=2$ can be found as

$$
\lambda^{2}-\operatorname{trace}(A) \lambda+\operatorname{det}(A)=0
$$

5. Remark. For $n \times n$ matrix the characteristic equation is a polynomial equation of degree $n$. The eigenvectors corresponding to $\lambda$ can be found by solving the corresponding system of linear equations $(A-\lambda I) v=0$ (as we will see in the next examples).
6. Example. Find eigenvalues and eigenvectors of the matrix $A=\left(\begin{array}{cc}-2 & 1 \\ 2 & -3\end{array}\right)$.
7. Example. Given

$$
A=\left(\begin{array}{ccc}
1 & -1 & 4 \\
3 & 2 & -1 \\
2 & 1 & -1
\end{array}\right)
$$

(a) Find eigenvalues of $A$.
(b) Find eigenvectors of $A$ (use Gauss Elimination Method below).

## Gauss Elimination Method

8. The Gauss Method is a suitable technique for solving systems of linear equations of any size. A sequence of operations (see below) of the Gauss-Jordan elimination method allows us to obtain at each step an equivalent system - that is, a system having the same solution as the original system.

The operations of the Gauss-Jordan elimination method are
(a) Interchange any two equations.
(b) Replace an equation by a nonzero multiple of itself.
(c) Replace an equation by itself plus a nonzero multiple of any other equation.
9. An augmented matrix that is formed by combining the coefficient matrix and the constant matrix. For example, for the system of linear equations $\left\{\begin{array}{l}3 x_{1}+12 x_{2}=20 \\ 2 x_{2}=x_{1}+7\end{array}\right.$ the augmented matrix is $\left(\begin{array}{cc|c}3 & 12 & 10 \\ 1 & -2 & 7\end{array}\right)$.
10. The goal of the Gauss Elimination Method is to get the augmented matrix into Reduced Echelon Form. A matrix is in row echelon form if

- All nonzero rows (rows with at least one nonzero element) are above any rows of all zeroes (all zero rows, if any, belong at the bottom of the matrix).
- The leading coefficient (the first nonzero number from the left, also called the pivot) of a nonzero row is always strictly to the right of the leading coefficient of the row above it.
- All entries in a column below a leading entry are zeroes (implied by the first two criteria).

11. To put a matrix in Reduced Form, there are three valid Row Operations:
(a) Interchange any two rows $\left(R_{i} \leftrightarrow R_{j}\right)$.
(b) Replace any row by a nonzero constant multiple of itself ( $R_{i} \leftrightarrow c R_{i}$ ).
(c) Replace any row by the sum of that row and a constant multiple of any other row $R_{i} \leftrightarrow\left(R_{i}+c R_{j}\right)$.
