### 27 Lines on a Cubic Surface

A cubic surface is the set of solutions

$$V(F) := \{x \mid F(x) = 0\}$$

of a cubic polynomial F in 3-space.

[Technicality: F is homogeneous in (x, y, z, w) and  $\mathcal{V}(F)$  is a subset of projective space  $\mathbb{P}^3$ .]

By the classical theorem of Cayley and Salmon (1849), there are exactly 27 lines on a smooth cubic surface  $\mathcal{V}(F) \subset \mathbb{P}^3$ .

Shläfli (1858) showed that these lines have a remarkable incidence configuration with symmetry group that we now call  $E_6$ .

#### 27 Lines on a Cubic Surface

In 1870, Camille Jordan wrote the first book on Galois theory, *Traité des substitutions et des équations*. In it, he related the 27 lines to Galois theory.

Galois theory arose from the ancient problem of finding roots of a univariate polynomial. Galois's revolutionary work studied finite extensions  $\mathbb{L}/\mathbb{K}$  of fields via their symmetry (Galois) groups—automorphisms of  $\mathbb{L}$  that fix  $\mathbb{K}$  pointwise.

Suppose that F has rational  $(\mathbb{Q})$  coefficients and let K be the field of definition of the lines on  $\mathcal{V}(F)$ . Then  $K/\mathbb{Q}$  is a Galois extension, and its Galois group  $\operatorname{Gal}(K/\mathbb{Q})$  acts on the 27 lines.

In fact, Jordan showed that this action is faithful,  $Gal(K/\mathbb{Q}) \subset E_6$ .

#### Modern View

Let us work over  ${\mathbb C}$  and consider the incidence variety,

$$\Gamma:=\{(\ell,F)\in\mathbb{G}(1,\mathbb{P}^3) imes\mathbb{P}^{19}_{ ext{cubics}}\,:\,F|_\ell\equiv 0\}\,.$$

$$\downarrow^{\mathfrak{P}^{19}_{ ext{cubics}}}$$

The extension  $\mathbb{C}(\Gamma)/\mathbb{C}(\mathbb{P}^{19})$  of function fields has degree 27, and if K is the Galois closure of  $\mathbb{C}(\Gamma)/\mathbb{C}(\mathbb{P}^{19})$ , then  $\mathrm{Gal}(K/\mathbb{C}(\mathbb{P}^{19}))=E_6$ . (Many proofs were given in the 20th century.)

Over the locus of smooth cubics (open and dense in  $\mathbb{P}^{19}$ ), this is a covering space of degree 27.

Its monodromy group is also  $E_6$ .

 $\Gamma \to \mathbb{P}^{19}$  is a branched cover of degree 27 (see next slide).

## **Enumerative Geometry**

Enumerative Geometry is the art of determining the number d of geometric figures x having specified positions with respect to other, fixed figures b. — Schubert (1879)

Example: Lines lying on a cubic surface.

X:= the space of the figures x we count, and B:= configuration space of the fixed figures. The *incidence variety*  $\Gamma \subset X \times B$  consists of pairs (x,b) where  $x \in X$  has the specified position with respect to  $b \in B$ .

The projection  $\Gamma \to B$  has degree d, as its fibers are the solutions.

More generally, a branched cover is a dominant map  $\pi \colon \Gamma \to B$  of irreducible varieties of the same dimension. Let d be its degree.

Branched covers appear in applications as families (incidence varieties) of systems of polynomial equations.

## Galois = Monodromy

Let  $\pi \colon \Gamma \to B$  be a branched cover of degree d. Then the extension  $\mathbb{C}(\Gamma)/\mathbb{C}(B)$  of function fields has degree d.

Let K be the Galois closure of the field extension  $\mathbb{C}(\Gamma)/\mathbb{C}(B)$ . The Galois group of  $\pi$  is  $\mathrm{Gal}_{\pi} := \mathrm{Gal}(K/\mathbb{C}(B))$ .

There is an open dense subset of B over which  $\pi$  is a covering space of degree d. Let  $\mathsf{Mon}_\pi$  be the monodromy group.

Both  $Gal_{\pi}$  and  $Mon_{\pi}$  are transitive subgroups of the symmetric group  $S_d$ , well-defined up to conjugation.

<u>Theorem</u>. [Hermite 1851 · · · · Harris 1979 SGA1 V.8.2 1961]  $Gal_{\pi} = Mon_{\pi}$ .

This has an interesting story.

## Harris's Principle

In Galois groups in enumerative geometry (1979), Harris studied Galois groups of many enumerative problems. Like the 27 lines, some had small (not equal to symmetric group) Galois groups, and he showed this was explained by structure among their solutions.

He showed that others—such as the problem of 3264 conics—were fully symmetric and had no apparent structure.

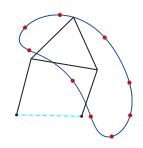

Harris's Principle: An (enumerative) Galois group should be as large as possible, given the structure of its solutions.

A Galois/monodromy group that is not fully symmetric is *enriched*, as the solutions (should be) enriched with extra structure.

Examples of this are in the beautiful paper of Hashimoto and Kadets: 38406501359372282063949 & all that: Monodromy of Fano Problems.

### Some Enriched Problems

The four bar synthesis problem of Alt is to find the four bar mechanisms whose coupler curve passes through 9 points in the plane. The Roberts-Chebyschev Theorem reveals a hidden symmetry: each coupler curve is generated by three cognate linkages.

Standard formulations have left $\leftrightarrow$ right label-swapping, which implies that the Galois group is enriched, lying in  $(\mathbb{Z}/3\mathbb{Z}\times\mathbb{Z}/2\mathbb{Z})^{1442}\rtimes\mathcal{S}_{1442}$ .

Minimal vision problems include some which are enriched (which is exploited for solving).

There are many other examples from applications. To paraphrase Joos Heintz: "You may not care about Galois, but Galois cares about you(r problems)".

## Sparse Polynomial Systems

Let  $\mathcal{A} \subset \mathbb{Z}^n$  be exponents for monomials in  $x_1, \ldots, x_n$ . Then

$$f = \sum_{a \in \mathcal{A}} c_a x^a \qquad (c_a \in \mathbb{C})$$

is a sparse polynomial with support  $\mathcal{A}$ . These form the vector space  $\mathbb{C}^{\mathcal{A}}$ .

Given a list  $\mathcal{A}_{\bullet} = (\mathcal{A}_1, \dots, \mathcal{A}_n)$  of supports, consider  $\mathbb{C}^{\mathcal{A}_{\bullet}} := \text{space of polynomials } (f_1, \dots, f_n) \text{ with } \mathcal{A}_i = \text{support of } f_i.$ 

Bernstein-Kuchnirenko Theorem. The number of solutions in  $(\mathbb{C}^{\times})^n$  to a system  $f_1 = \cdots = f_n = 0$  of polynomials with support  $A_{\bullet}$  is  $\mathsf{MV}(A_{\bullet})$ , the mixed volume of the convex hulls of the  $A_i$ .

Let  $\Gamma \subset (\mathbb{C}^{\times})^n \times \mathbb{C}^{\mathcal{A}_{\bullet}}$  be the corresponding incidence variety. Then  $\Gamma \to \mathbb{C}^{\mathcal{A}_{\bullet}}$  is a branched cover of degree  $\mathsf{MV}(\mathcal{A}_{\bullet})$ .

Let  $\mathrm{Gal}_{\mathcal{A}_{\bullet}}$  be the Galois group of this branched cover of systems with support  $\mathcal{A}_{\bullet}.$ 

### Esterov's Theorem

There are two obvious ways for  $Gal_{A_{\bullet}} \neq S_{MV(A_{\bullet})}$ :

Lacunary: f(x) has the form  $g(x^3)$ .

Triangular: The system is f(x, y) = g(y) = 0.

For both, the system is solved in stages, which implies that  $\operatorname{Gal}_{\mathcal{A}_{\bullet}}$  lies in a wreath product, so that it is imprimitive and is not the full symmetric group.

Esterov's Theorem.  $Gal_{\mathcal{A}_{\bullet}} = \mathcal{S}_{MV(\mathcal{A}_{\bullet})}$  unless  $\mathcal{A}_{\bullet}$  is lacunary or triangular.

 $\leadsto$  Esterov and Lang showed that it is not clear what  $Gal_{\mathcal{A}_{\bullet}}$  is.

You may exploit the imprimitivity given by Esterov's Theorem for solving, even when  $Gal_{\mathcal{A}_{\bullet}}$  is unknown. (Joint work with Brysiewicz, Rodriguez, and Yahl.)

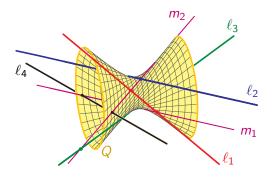

Frank Sottile, Texas A&M University

What are the lines  $m_i$  meeting four general lines  $\ell_1, \ell_2, \ell_3$ , and  $\ell_4$ ?

What are the lines  $m_i$  meeting four general lines  $\ell_1, \ell_2, \ell_3$ , and  $\ell_4$ ?  $\ell_1, \ell_2, \ell_3$  lie on a unique hyperboloid Q of one sheet, and the lines meeting them form one ruling of Q.

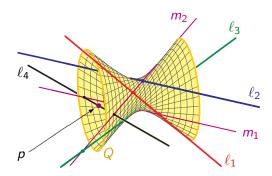

What are the lines  $m_i$  meeting four general lines  $\ell_1, \ell_2, \ell_3$ , and  $\ell_4$ ?  $\ell_1, \ell_2, \ell_3$  lie on a unique hyperboloid Q of one sheet, and the lines meeting them form one ruling of Q. The solutions  $m_i$  are the lines in that ruling passing through the points of intersection  $\ell_4 \cap Q$ .

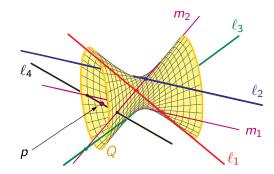

What are the lines  $m_i$  meeting four general lines  $\ell_1, \ell_2, \ell_3$ , and  $\ell_4$ ?  $\ell_1, \ell_2, \ell_3$  lie on a unique hyperboloid Q of one sheet, and the lines meeting them form one ruling of Q. The solutions  $m_i$  are the lines in that ruling passing through the points of intersection  $\ell_4 \cap Q$ .

Rotating the line  $\ell_4$  180° around the point p interchanges the two solution lines  $m_1$ ,  $m_2$ .

What are the lines  $m_i$  meeting four general lines  $\ell_1, \ell_2, \ell_3$ , and  $\ell_4$ ?  $\ell_1, \ell_2, \ell_3$  lie on a unique hyperboloid Q of one sheet, and the lines meeting them form one ruling of Q. The solutions  $m_i$  are the lines in that ruling passing through the points of intersection  $\ell_4 \cap Q$ .

Rotating the line  $\ell_4$  180° around the point p interchanges the two solution lines  $m_1$ ,  $m_2$ .

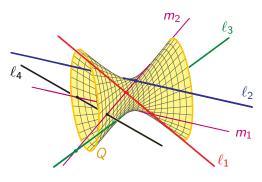

This shows that

The Galois group of the problem of four lines is the symmetric group  $S_2$ .

#### Schubert Problems

The Schubert calculus is an algorithmic method of Schubert to solve a wide class of problems in enumerative geometry.

Schubert problems are enumerative problems involving linear subspaces of a vector space incident upon other linear spaces, such as the problem of four lines. They take place on a Grassmannian, G(k, n) of k-planes in  $\mathbb{C}^n$ .

As there are many millions of computable Schubert problems, many with their own unique geometry, they provide a rich and convenient laboratory for studying Galois groups of geometric problems.

## Schubert Galois Groups

c. 2003 Vakil's Method can show that a Schubert Galois group is at least alternating. All problems on G(2, n) for  $n \le 16$  and on G(3, n) for  $n \le 9$  are at least alternating.

Derksen and Vakil constructed enriched problems, from G(4,8) up. These have Galois group  $S_n \subset S_{\binom{n}{k}}$  (acting on k-subsets of [n]).

2009: With Leykin: Using numerical methods, many simple Schubert problems are fully symmetric, including one with 17,589 solutions.

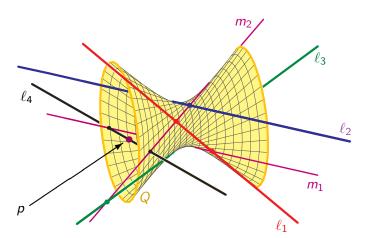

2012: With Brooks and Martín del Campo: All Schubert problems on G(2, n) are at least alternating.

2015: With White: All Schubert problems on G(3, n) are 2-transitive.

2019: With Martín del Campo and Williams: Classified all Schubert problems on G(4,8) and G(4,9). Most (99.5%) are at least alternating.

Those that are not fall into three geometrically distinct families.

# Thank You!

## Transitive Permutation Groups

A permutation group  $H \subset \mathcal{S}_d$  has an action on [d]. It is transitive if it has only one orbit on [d]. It is t-transitive if it has only one orbit on  $[d]^t \setminus \Delta$  (the complement of the diagonal).

There are few highly (t > 2) transitive permutation groups.

H is *primitive* is it preserves no nontrivial partition of [d].

Otherwise, H is imprimitive.

When H is imprimitive,  $d = a \cdot b$  (1 < a, b), so that  $[d] = [a] \times [b]$ .

Furthermore, the action of H preserves the fibration  $[a] \times [b] \to [a]$ .

Then H lies in the wreath product  $(S_b)^a \rtimes S_a$ .

## Derksen's example

Q: What 4-planes H in  $\mathbb{C}^8$  that meet each of general 4-planes  $K_1, K_2, K_3, K_4$  in a 2-dimensional subspace?

Auxiliary problem: There are four  $(h_1, h_2, h_3, h_4)$  2-planes in  $\mathbb{C}^8$ meeting each of  $K_1, K_2, K_3, K_4$ . Schematically,  $\blacksquare \blacksquare \blacksquare = 4$ .

Fact: All solutions H to our problem have the form  $H_{i,j} = \langle h_i, h_i \rangle$ 

for  $1 \le i < j \le 4$ . Schematically,  $\prod_{i=1}^{4} = 6$ .

It follows that the Galois group of = 6 is equal to the Galois group of = 4, which is known to be the symmetric group  $S_4$ .

This problem = 6 also has exceptional reality: If  $K_1, K_2, K_3, K_4$  are real, then either two or six of the  $H_{i,i}$  are real, and never four or zero.

## Known Schubert Galois Groups

#### The three families:

- (1) For  $1 \leq k < n$ , the problem of 2k-planes in  $\mathbb{C}^{2n}$  meeting 4  $\mathbb{C}^n$ s in a  $\mathbb{C}^k$  has Galois group  $\mathcal{S}_n \subset \mathcal{S}_{\binom{n}{k}}$ . Call this  $\mathcal{G}\binom{n}{k}$ .
- (2) For Schubert problems  $\lambda$  on G(k, n) and  $\mu$  on G(l, m), there is a new Schubert problem  $\lambda \circ \mu$  on G(k + l, n + m).

The number,  $d(\lambda \circ \mu)$  of solutions is the product  $d(\lambda) \cdot d(\mu)$  and  $\mathsf{Gal}_{\lambda \circ \mu} \subseteq (\mathsf{Gal}_{\mu})^{d(\lambda)} \rtimes \mathsf{Gal}_{\lambda}$ .

(3) There is a third, less-understood class.

All known Schubert Galois groups are iterated wreath products of the  $\mathcal{G}\binom{n}{l}$ .

Conjecture. These are the only Schubert Galois groups.

Hope. Enriched Schubert problems can be classified.

(2) is work with Williams and Ying, and involves interesting combinatorics.
