## Lecture 13: <br> Bifurcation theory.

## Bifurcation theory

The object of bifurcation theory is to study changes that maps undergo as parameters change.
In the context of one-dimensional dynamics, we consider a one-parameter family of maps $f_{\lambda}: \mathbb{R} \rightarrow \mathbb{R}$. We assume that $G(x, \lambda)=f_{\lambda}(x)$ is smooth a function of two variables. Informally, the family $\left\{f_{\lambda}\right\}$ has a bifurcation at $\lambda=\lambda_{0}$ if the dynamics of $f_{\lambda}$ changes as $\lambda$ passes $\lambda_{0}$. One way to formalize it is to require that there exist $\varepsilon>0$ such that for any $\varepsilon_{1}, \varepsilon_{2} \in(0, \varepsilon)$ the maps $f_{\lambda_{0}-\varepsilon_{1}}$ and $f_{\lambda_{0}+\varepsilon_{2}}$ are not topologically conjugate. The simplest case is an isolated bifurcation point $\lambda_{0}$. In this case, the map $f_{\lambda}$ is structurally stable for all $\lambda$ in a punctured neighborhood of $\lambda_{0}$ but not for $\lambda=\lambda_{0}$.
The condition of topological conjugacy is often relaxed to local topological conjugacy or to similar configuration of periodic orbits.

## Saddle-node bifurcation

Exponential map $E_{\lambda}(x)=\lambda e^{x}, \quad \lambda \approx 1 / e, \quad x \approx 1$.

For $\lambda>1 / e$, there are no fixed points. At $\lambda=1 / e$, there is a non-hyperbolic fixed point 1 . For $0<\lambda<1 / e$, there are two fixed points, one is repelling and the other one is attracting.

## Saddle-node bifurcation

Exponential map $E_{\lambda}(x)=\lambda e^{x}, \quad \lambda \approx 1 / e, \quad x \approx 1$.

$\qquad$

## Bifurcation diagram (saddle-node bifurcation)

In the plane with coordinates $(\lambda, x)$, we plot fixed points of $E_{\lambda}$ for each $\lambda$ :

## Period doubling bifurcation

Exponential map $E_{\lambda}(x)=\lambda e^{x}, \lambda \approx-e, \quad x \approx-1$.

For $-e<\lambda<0$, the fixed point is attracting. At $\lambda=-e$, it is not hyperbolic. For $\lambda<-e$, the fixed point is repelling and there is also an attracting periodic orbit of period 2.

## Bifurcation diagram (period doubling bifurcation)

In the plane with coordinates $(\lambda, x)$, we plot fixed points of $E_{\lambda}^{2}$ for each $\lambda$ :

## Period doubling: logistic map

Logistic map $F_{\mu}(x)=\mu x(1-x), \mu \approx 3, x \approx 2 / 3$.
Consider graphs of $F_{\mu}^{2}$ for $\mu \approx 3$ :

For $\mu<3$, the fixed point $p_{\mu}=1-\mu^{-1}$ is attracting. At $\mu=3$, it is not hyperbolic. For $\mu>3$, the fixed point $p_{\mu}$ is repelling and there is also an attracting periodic orbit of period 2.

## No bifurcation: sufficient condition

Theorem 1 Let $f_{\lambda}$ be a one-parameter family of functions and suppose that $f_{\lambda_{0}}\left(x_{0}\right)=x_{0}$ and $f_{\lambda_{0}}^{\prime}\left(x_{0}\right) \neq 1$. Then there are open intervals $I \ni x_{0}$ and $N \ni \lambda_{0}$ and a smooth function $p: N \rightarrow I$ such that $p\left(\lambda_{0}\right)=x_{0}$ and $f_{\lambda}(p(\lambda))=p(\lambda)$ for all $\lambda \in N$. Moreover, $p(\lambda)$ is the only fixed point of $f_{\lambda}$ in $I$.

## No bifurcation: sufficient condition

Theorem 1 Let $f_{\lambda}$ be a one-parameter family of functions and suppose that $f_{\lambda_{0}}\left(x_{0}\right)=x_{0}$ and $f_{\lambda_{0}}^{\prime}\left(x_{0}\right) \neq 1$. Then there are open intervals $I \ni x_{0}$ and $N \ni \lambda_{0}$ and a smooth function $p: N \rightarrow I$ such that $p\left(\lambda_{0}\right)=x_{0}$ and $f_{\lambda}(p(\lambda))=p(\lambda)$ for all $\lambda \in N$. Moreover, $p(\lambda)$ is the only fixed point of $f_{\lambda}$ in $I$.

Proof: Consider a function of two variables $G(x, \lambda)=f_{\lambda}(x)-x$. We have $G\left(x_{0}, \lambda_{0}\right)=f_{\lambda_{0}}\left(x_{0}\right)-x_{0}=0$ and $\frac{\partial G}{\partial x}\left(x_{0}, \lambda_{0}\right)=f_{\lambda_{0}}^{\prime}\left(x_{0}\right)-1 \neq 0$. By the Implicit Function Theorem, there are open intervals $I \ni x_{0}$ and $N \ni \lambda_{0}$ and a smooth function $p: N \rightarrow I$ such that

$$
G(x, \lambda)=0 \Longleftrightarrow x=p(\lambda) \text { for all }(x, \lambda) \in I \times N
$$

## Saddle-node bifurcation: sufficient condition

Theorem 2 Let $f_{\lambda}$ be a one-parameter family of functions and suppose that $f_{\lambda_{0}}\left(x_{0}\right)=x_{0}, f_{\lambda_{0}}^{\prime}\left(x_{0}\right)=1, f_{\lambda_{0}}^{\prime \prime}\left(x_{0}\right) \neq 0$, and $\left.\frac{\partial f_{\lambda}}{\partial \lambda}\right|_{\lambda=\lambda_{0}}\left(x_{0}\right) \neq 0$. Then there are open intervals $I \ni x_{0}$ and $N \ni \lambda_{0}$ and a smooth function $p: I \rightarrow N$ such that $p\left(x_{0}\right)=\lambda_{0}$ and $f_{p(x)}(x)=x$ for all $x \in I$. Moreover, $p^{\prime}\left(x_{0}\right)=0$ and $p^{\prime \prime}\left(x_{0}\right) \neq 0$.

## Period doubling bifurcation: sufficient condition

Theorem 3 Let $f_{\lambda}$ be a one-parameter family of functions and suppose that $f_{\lambda}\left(x_{0}\right)=x_{0}$ for all $\lambda, f_{\lambda_{0}}^{\prime}\left(x_{0}\right)=-1$, and $\left.\frac{\partial\left(f_{\lambda}^{2}\right)^{\prime}}{\partial \lambda}\right|_{\lambda=\lambda_{0}}\left(x_{0}\right) \neq 0$. Then there are open intervals $I \ni x_{0}$ and $N \ni \lambda_{0}$ and a smooth function $p: I \rightarrow N$ such that $p\left(x_{0}\right)=\lambda_{0}$ and $f_{p(x)}^{2}(x)=x$ for all $x \in I$ but $f_{p(x)}(x) \neq x$ for $x \in I \backslash\left\{x_{0}\right\}$.

## More examples

- Quadratic maps: $Q_{c}(x)=x^{2}+c$.

The family undergoes a saddle-node bifurcation at $c=1 / 4$ and a period doubling bifurcation at $c=-3 / 4$. It undergoes a lot of other bifurcations as well.

- Hyperbolic sine family: $H_{\lambda}(x)=\lambda \sinh x$. A map $H_{\lambda}$ is not structurally stable within the family for $\lambda=-1,0$, and 1 . At $\lambda=-1$, we have a period doubling bifurcation. At $\lambda=1$, the family transitions from one to three fixed points. At $\lambda=0$, the bifurcation does not change the configuration of periodic points.
- Linear maps: $f_{\lambda}(x)=\lambda^{2} x$.

A map $f_{\lambda}$ is not structurally stable within the family for $\lambda=-1,0$, and 1 . At $\lambda=-1$ and 1 , the family transitions from a repelling fixed point to an attracting one (or vice versa). At $\lambda=0$, there is no bifurcation.
